NOTICE

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our knowledge, changes in practice, treatment and drug therapy may become necessary or appropriate. Readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of the practitioner, relying on their own experience and knowledge of the patient, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions. To the fullest extent of the law, neither the Publisher nor the [Editors/Authors] [delete as appropriate] assumes any liability for any injury and/or damage to persons or property arising out or related to any use of the material contained in this book.

Library of Congress Cataloging-in-Publication Data

Disaster medicine/editor-in-chief, Gregory R. Ciottone; associate editors, Philip D. Anderson ... [et al.]; section editors, Kathryn Brinsfield ... [et al].-1st ed.

p.; cm.

Includes bibliographical references and index.

CONTENTS

PART I • Overview of Disaster Management

- 1** Introduction to Disaster Medicine 3
Gregory R. Ciottone

Section One • Introduction

- 2** Public Health and Disasters 7
Catherine Y. Lee and James Michael Riley
- 3** The Role of Emergency Medical Services (EMS) in Disaster 20
Robert D. Furberg and David E. Marcozzi
- 4** Role of Emergency Medicine in Disaster Management 26
Andrew I. Bern
- 5** The Role of Hospitals in Disaster 34
Mary W. Chaffee and Neill S. Oster
- 6** Complex Emergencies 43
Frederick M. Burkla, Jr. and P. Gregg Greenough
- 7** Children and Disaster 51
Bruce M. Becker
- 8** Psychological Impact of Disaster 59
Tracy E. Wimbush and Christo C. Courban
- 9** Ethical Issues in the Provision of Emergency Medical Care in Multiple Casualty Incidents and Disasters 63
Pinchas Halpern and Gregory L. Larkin
- 10** Liability Issues in Emergency Response 71
Abigail Williams

Section Two • Governmental Resources

- 11** Disaster Response in the United States 79
Jerry L. Mothershead
- 12** Local Disaster Response 84
Jerry L. Mothershead
- 13** Disaster Planning: State Programs and Response 90
Esther H. Chen, Bruce Y. Lee, and Jerry L. Mothershead
- 14** Selected Federal Disaster Response Agencies and Capabilities 95
Jerry L. Mothershead, Kevin Yeskey, and Peter Brawster
- 15** International Disaster Response 102
Oan Hanfling, Craig H. Llewellyn, and Frederick M. Burkla, Jr.
- 16** Disaster/Emergency Management Programs 108
Peter Brawster

Section Three • Pre-Event Topics

- 17** Community Hazard Vulnerability Assessment 112
James C. Chang
- 18** Health Care Facility Hazard and Vulnerability Analysis 117
James C. Chang, William Gluckman, and Eric S. Weinstein
- 19** Public Information Management 124
Sharon Dilling, William Gluckman, Marc S. Rosenthal, and Eric S. Weinstein
- 20** Informatics and Telecommunications in Disaster 130
Churton Budd
- 21** Disaster Mitigation 139
Robert M. Gougelet
- 22** Vaccines 145
Kent J. Stock
- 23** Occupational Medicine: An Asset in Time of Crisis 152
Tee L. Guidotti

P R E F A C E

Walking slowly toward Ground Zero as Commander of one of the first Federal Disaster Medical Assistance Teams into the World Trade Center disaster, I was initially struck by a sense of helplessness at the sight of the devastation. As the plumes of smoke rose from the undulating piles of destruction, we had a sense that the disaster before us was so vast and our task so enormous that we would never be able to mount an effective response. This feeling of helplessness did not abate until we resorted to our training and took up our role in the overall disaster response. We were a cog in a very large machine, placed precisely where we would be supported by the other parts, and function in such a specialized way as to keep the machine running. At that moment of realization, this book was born.

The philosophy behind the writing of this textbook is to bring resources together necessary for the development of a comprehensive understanding of Disaster Medicine and its role in Disaster Management. The release of the book comes soon after Hurricane Katrina has devastated the Gulf Coast of America and approximately 1 year after the horror of the Southeast Asia tsunami. After witnessing the devastation of vast areas around the Indian Ocean, and the destruction of a major U.S. city, it is impossible not to be struck by the destructive powers of such natural events. There is, however, another striking feature about both of these events. Whereas the tsunami struck some of the poorest areas, Katrina struck the most developed and richest country in the world. Regardless of these stark socio-economic contrasts, the destruction to the affected areas was remarkably similar: it was nearly total. Disaster strikes without warning, is indiscriminate in its choice of victims, and has the potential of overcoming even the most prepared of systems. If there is no other justification for a book such as this, it must be said that these recent events demand that we, as healthcare professionals, develop an understanding of the basics of Disaster Medicine and stand ready to integrate into the response system if and when disaster should strike close to home.

This book is designed to serve as both a comprehensive text and a quick resource. Part 1 introduces the many topics of disaster medicine and management with an emphasis on the multiple disciplines that come together in the preparation for and response to such catastrophic events. It is the integration of these various response and preparedness modalities that makes Disaster Medicine such a unique field. This section is meant to be a comprehensive approach to the study of the discipline of Disaster Medicine and should be used by healthcare professionals to develop and expand their knowledge base. The chapters may introduce topics that

are unfamiliar to the reader, as most practitioners will not be versed in some of the non-medical subjects discussed. Although much of the information may be very new, it may also be crucial in the unexpected event a disaster strikes nearby.

Part 2 of the book, or the “Event” chapters, introduces the reader to every conceivable disaster scenario, and the management issues surrounding each. This part of the text can be used as both a reference and a real-time consult for each topic. The reader will find very detailed and specific events described in these chapters. Some disaster scenarios discussed have historical precedence whereas others are considered to be at risk for future occurrence. Many describe natural and accidental events while some are dedicated to very specific terrorist attacks. There is no easy way to discuss these topics. In particular, terrorist events may cause a sense of unease as one reads the chapter. The chapters related to terrorism in this section attempt to account for every possible modality terrorist operatives are thought to currently possess or may acquire in the future. In some cases the scenarios may prove true, and in many they may not. It is imperative, however, that all possible modalities of attack be discussed so that if needed, proper preparedness and response can be mounted. The term “attack” has been deliberately used in many of these chapters to emphasize the point that, if these agents and scenarios are purposefully unleashed, it will, in fact, be in the form of an attack. The need for inclusion of such terminology in an academic medical textbook underscores the climate in which this text has been written. After such events as the Sept. 11, 2001 attacks, the elementary school tragedy in Beslan, Russia, and the London bombings of 2005, the clear need for thorough discussion is apparent. Part 2 of this text discusses these scenarios in as complete a way as possible, while respecting the dignity of those afflicted by past events. In a way it is the pain and suffering of both victims and survivors of such events that has contributed most to this text, and it is in celebration of their spirit that it has been written.

Finally, I must mention the outstanding group of editors and contributors you will find within these pages. I went to great lengths to find individuals who are expert in their field, not only because they have studied it, but because they have done it. These are the doers as well as the thinkers. These are the men and women who leave their families when disaster strikes and integrate into the response systems. They are the experts called upon on a regional, national, and international level to prepare for disasters, always learning from the past and planning for the future. This book is more than 2 years in the making, partly because during that time the editors and authors

were all too often deployed for lengthy periods into disaster zones around the world. In the study of Disaster Medicine, perhaps like none other, knowledge borne from experience makes for a very robust textbook. You will feel that experience jump from these pages and you will be rewarded by having learned from the best.

Because of the ubiquitous nature of disaster, society is indebted to those who choose to learn and practice this field. As a member of that society, I would like to personally thank you for doing so.

Gregory R. Ciottone, MD, FACEP

Introduction to Disaster Medicine

Gregory R. Ciottone

Throughout history, emergency medical responders have cared for the victims of disaster. As in other areas of disease and injury, medical personnel assume the responsibility of providing care to patients with illness or injury resulting from the catastrophe. Unlike other areas of medicine, however, the care of casualties from a disaster requires the healthcare provider to integrate into the larger, predominantly non-medical multidisciplinary response. This demands a knowledge base far greater than medicine alone. To operate safely and efficiently as part of a coordinated disaster response, either in a hospital or in the field, an understanding of disaster management principles is necessary.

In the mid-1980s, disaster medicine began to evolve from the union of disaster management and emergency medicine. Although Disaster Medicine is not yet an accredited medical subspecialty, those who practice it have been involved in some of the most catastrophic events in human history. Practitioners of present day disaster medicine have responded to the aftermaths of the tsunami in southeast Asia,¹ hurricane Andrew,² the Indian earthquake,³ the Madrid train bombings,⁴ and the World Trade Center attack,⁵ to name a few. During the past several decades, the first applications of basic disaster medicine principles in real-time events have been carried out, and as demonstrated recently by the 2004 tsunami in southeast Asia, there is sure to be continued need for such applications.

The impetus for this text grew from a realization that, as the specialty of emergency medicine grows, emergency physicians must take ownership of this new field of disaster medicine and ensure it meets the rigorous demands put upon it by the very nature of human disaster. If we are to call ourselves disaster medicine specialists and are to be entrusted by society to respond to the most catastrophic human events, it is imperative that we pursue the highest level of scholarly knowledge in this very dynamic area. Until there is oversight from a certifying board, it is our responsibility to the public we serve to maintain this high level of excellence.

THE DISASTER CYCLE

Because disasters strike without warning in areas often unprepared for such events, it is essential for all emergency services personnel to have a foundation in the

practical aspects of disaster preparedness and response. As is discussed in other chapters throughout this text, emergency responders have an integrated role in disaster management. All disasters follow a cyclical pattern known as the *disaster cycle* (Fig. 1-1), which describes four reactionary stages: preparedness, response, recovery, and mitigation/prevention. Emergency medicine specialists have a role in each part of this cycle. As active members of their community, emergency specialists should take part in mitigation and preparedness on the hospital, local, and regional levels. Once disaster strikes, their role continues into the response and recovery phases. By participating in the varied areas of disaster preparation and response, including hazard vulnerability analyses, resource allocation, and creation of disaster legislation, the emergency medicine specialist integrates into the disaster cycle as an active participant. A thorough understanding of the disaster medicine needs of a community allows one to contribute to the overall preparedness and response mission.

NATURAL AND MANMADE DISASTER

Over the course of recorded history, natural disasters have predominated in frequency and magnitude over manmade ones. Some of the earliest disasters have caused enormous numbers of casualties, with resultant disruption of the underlying community infrastructure. *Yersinia pestis* caused the death of countless millions in several epidemics over hundreds of years. The etiological agent of bubonic plague, *Y. pestis* devastated Europe by killing large numbers of people and leaving societal ruin in its wake.⁶ As of this writing, there is fear of an impending avian influenza pandemic that may be worldwide in scale.⁷ Influenza and severe acute respiratory syndrome (SARS) have proven in recent years that, despite the passage of time and the great advances in medicine, the world continues to be affected by the outbreak of disease. Further, diseases that have been eradicated, such as smallpox, now have the potential of being reintroduced into society, either accidentally from the few remaining research sources in existence or by intentional release. Such an event could be devastating, as the baseline intrinsic immunity

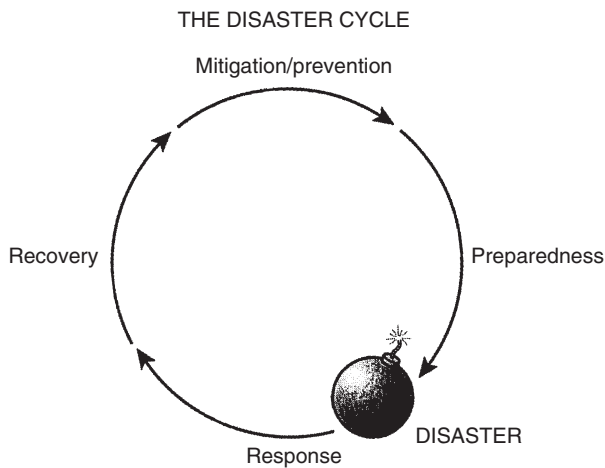

FIGURE 1-1. The disaster cycle.

the world population had developed during the natural presence of the disease has faded over time, putting much larger numbers of people at risk. Finally, with the advent of the airliner allowing rapid travel to any part of the world, the bloom effect of an outbreak is much harder to predict and control. Disease outbreaks that were previously controlled by natural borders, such as oceans, no longer have those barriers, making the likelihood of worldwide outbreak much greater now than it was hundreds of years ago.

In addition to epidemics, with each passing year natural disasters in the form of earthquakes, floods, and deadly storms batter populations. One need only to remember the destruction in terms of both human life and community resources caused by the Indian Ocean earthquake and subsequent tsunamis of 2004 to understand the need for preparedness and response to such natural events. Considering the earthquake that caused the tsunami occurred hours before the devastation, it is difficult to understand how today's advanced society, able to travel far into space among other great achievements, was unable to detect one of the most deadly natural events in recent history. The realization that disaster can strike without warning and inflict casualties on the order of the 2004 tsunami, despite our many technological advances, serves as a warning that mitigation, preparedness, and response to natural disaster must continue to be studied and practiced vigorously.

Today, the possibility of terrorist attack threatens populations across the globe. Both industrialized and developing countries have witnessed some of the most callous and senseless taking of life, for reasons not easily fathomed by civilized people. It is unusual to read a newspaper, listen to radio, or watch television news reports without learning of a terrorist attack in some part of the world. These attacks are so frequent that society has become almost numb to them. Today, an event such as a car bombing may be relegated to a side report on a daily newscast. The commonplace nature of a terrorist attack in modern society ensures it is unquestionably something that will continue long into the

future and will very likely escalate in scale and frequency.

The multilayered foundation on which ideological belief evolves into violent attack is beyond the scope of analysis this book ventures to undertake. These ongoing events do demonstrate, however, that the principles studied in the field of disaster medicine must include those that are designed to prepare for and respond to a terrorist attack. Because there are very intelligent minds at work designing systems to bring disaster on others, equally there must be as robust an effort to prepare for and respond to those disasters. Such response involves the deployment of law enforcement, evidence collection, and military personnel and equipment, which are typically not seen in the response to a natural disaster. The integration of these unique assets into the overall response is essential for the success of the mission. The disaster medicine specialist must have a thorough understanding of the role of each.

DEFINING DISASTER

A thorough discussion of disaster preparedness and response must be predicated on a clear definition of what, in fact, constitutes a disaster. Used commonly to describe many different events, disaster is not easily defined. One of the earliest documented testaments to such an event is that of the great flood, reported in several writings, including the *Bible*. This flood is described as covering vast areas of land in the most populated part of the ancient world. Such a flood would have killed millions of people and destroyed vast areas of inhabited land. This surely would fit the definition of a disaster. Similarly, the Indian Ocean tsunami in 2004, killing well over 200,000 people, would also meet the criteria for disaster. However, a 2005 bus crash in the Baharampur district of India that killed 48 people has also been called a disaster. Likewise, the 2003 explosion of the space shuttle Columbia on re-entry into Earth's atmosphere that killed the crew of seven astronauts onboard has often been referred to as the Columbia Disaster in the lay press. How can an event resulting in the loss of seven people be placed in the same category as one that kills hundreds of thousands? Herein lies the paradox of disaster. What is it? Who defines it and by what criteria?

It is difficult to dispute that an event causing thousands of casualties should be considered a disaster, but let's analyze why that is the case. What is it about the sheer number of dead and injured that allows the event to be called a disaster? In terms of medical needs, it is simply because there is no healthcare system on Earth that can handle that number of casualties. Therefore, an event of such magnitude is a disaster because it has overwhelmed the infrastructure of the community in which it occurred. Following this logic, we can then also make the statement that any event that overwhelms existing societal systems is a disaster. This definition is close to the United Nations Disaster Management Training Programme's (UNDMTP) definition of disaster⁸:

A disaster is a serious disruption of the functioning of a society, causing widespread human, material or environmental losses which exceed the ability of the affected society to cope using only its own resources.

A similar definition is used by the World Health Organization (WHO). By applying these definitions, one can understand how an event in a rural area with 10 to 20 casualties may also be considered a disaster because the limited resources in that area may prevent an adequate response without outside assistance.

The widely accepted UNDMTP and WHO definitions of disaster justify describing both the 2004 tsunami and the 2005 bus accident as disasters. But what about the space shuttle Columbia destruction on re-entry? Clearly this definition does not allow one to justify the use of disaster in describing that horrific accident. This brings to light a discrepancy in how disaster specialists and the lay public term events. The Columbia accident, as an example, does not meet any accepted criteria of disaster. It was, however, an exceedingly tragic event, seen by millions on television as it was unfolding. It was tragic by the word's very definition in the *Cambridge Dictionary*: "A very sad event, especially one involving death or suffering." Public perception of such events may cause this misnomer, with a tragic incident being termed a disaster. Much like disaster, tragedy can also have a profound and lasting effect on society, especially a tragedy that is widely viewed through modern media outlets. This text, however, will follow the UNDMTP and WHO definitions when discussing disaster.

DISASTER MEDICINE

Disaster medicine is a discipline resulting from the marriage of emergency medicine and disaster management. The role of medicine, in particular emergency medicine, in disaster response has been clearly defined throughout history. Responsibility for the care of the injured from a disaster has been borne by the emergency specialist. Therefore, disaster medical response, in its many forms, has been around for thousands of years. Whenever a disaster has struck, there has been some degree of a medical response to care for the casualties. In the United States, much of the disaster medical response has followed a military model, with lessons learned through battlefield scenarios during the last two centuries.⁹ The military experience has demonstrated how to orchestrate efficient care to mass casualties in austere environments. It does not, however, translate directly into civilian practice. For instance, scenarios encountered on the battlefield with young, fit soldiers injured by trauma are vastly different from those encountered in a rural setting, where an earthquake may inflict casualties on a population with baseline malnutrition or advanced age. With this realization came the need to create disaster medicine as an evolution from the military practice. This recent organization of the medical role in disasters into a more formalized specialty of disaster medicine has enabled practitioners to further define their role in the overall disaster preparedness and response system.

Disaster medicine is truly a systems-oriented specialty. There is no "disaster clinic." There are no practitioners who leave home in the morning intent on seeing disaster patients. Disaster medical care is often thrust upon the practitioner and is not necessarily something that is sought out. The exception to this is the medical specialist who becomes part of organized (usually federal) disaster team, such as a Disaster Medical Assistance team (DMAT). In this case, one may be transported to a disaster site with the intention of treating the victims of a catastrophic event. In all other circumstances, however, the disaster falls on an unsuspecting emergency responder who is forced to abandon his or her normal duties and adopt a role in the overall disaster response.

Unlike the organized disaster team member, if an emergency provider treats casualties from disaster, it will most likely be as a result of a disaster event that has occurred in his or her immediate area. Because of the random nature of disaster, it is not possible to predict who will be put into that role next. Therefore, it is imperative for all who practice in emergency health services to have a working knowledge of the basics of disaster medicine and disaster management. In addition, especially with the recent escalation in perceived and real terrorist threats, there are a host of possible attack scenarios, which may involve exotic chemical, biological, or nuclear agents and modalities. Most clinicians will have a very limited knowledge of many of these agents, so it is therefore important to educate our potential disaster responders on their specifics.

The field of disaster medicine involves the study of subject matter from multiple medical disciplines. Disasters may result in varying injury and disease patterns, depending on the type of event that has occurred. Earthquakes can cause entrapment and resultant crush syndrome; tornadoes may cause penetrating trauma from flying debris; and disease outbreak, either natural or intentional, can result from many different bacteria, viruses, and fungi. Because of the potential variability in casualty scenarios, the disaster medicine specialist must have training in the many injury and illness patterns seen in disaster victims. Even though the expanse of knowledge required is vast, the focus on areas specifically related to disaster medicine allows the science to be manageable. The study of disaster medicine should not be undertaken without prerequisite medical training. A disaster medicine specialist is always a practicing clinician from another field of medicine first and a disaster specialist second. By integrating these many disciplines, one is prepared for the variety of injury and illness patterns that may be faced.

Finally, disaster medicine presents unique ethical situations not seen in other areas of medicine. Disaster medicine is predicated on the principle of providing care to the most victims possible as dictated by the resources available and by patient condition and likelihood of survival. Disaster triage involves assigning patients into treatment categories based on their predicted survivability. This triage process may dictate that the most severely injured patient not be given medical care but rather it be provided to a less critically injured patient.

To the best of his or her ability, the triage officer must make a determination as to whether, in the environment of the specific disaster and the availability of resources, a given patient has a significant probability of survival or does not. If it is the latter, disaster triage principles mandate that care be given to the patient with a higher likelihood of survival. This basic disaster triage principle can have a profound psychological impact on the care provider. As a physician, one is trained to render care to the sick and to not leave the side of a needy patient. To deny care to a critically ill or injured patient can be one of the most anxiety-provoking tasks a disaster medicine specialist performs.

The unique and ever-changing circumstances under which disaster medicine specialists operate mandate the continued evolution and vigorous pursuit of academic excellence in this new specialty. A comprehensive approach that unifies medical principles with a sound understanding of disaster management procedures will yield a well-rounded and better-prepared disaster responder. If emergency medicine providers around the world can develop a basic understanding of the fundamental principles of this specialty, great advances in the systems included in the disaster cycle will surely follow. The more widely dispersed this knowledge becomes, the better prepared we are as a society to respond to the next catastrophic event.

chapter 2

Public Health and Disasters

Catherine Y. Lee and James Michael Riley

INTRODUCTION TO PUBLIC HEALTH

As early as 310 BC, a public health philosophy was exhibited by the Romans. They believed that cleanliness would lead to good health and made links between causes of disease and methods of prevention. For example, during this time an association was made between the increased death rate of persons living near swamps and sewage, and as a result the Roman Empire began working on two major public health projects in sanitation control: the building of aqueducts to supply clean water to the city and a sewage system to eliminate waste from the streets. Today, the benefits of public health infrastructure in the United States and abroad continue to strengthen the well-being of society. The impact of interventions has been great. In the past century (1900–1999), the 10 greatest public health achievements have been documented as the following¹:

1. Vaccination programs, meaning the eradication of smallpox; elimination of poliomyelitis in the Americas; and control of measles, rubella, tetanus, diphtheria, and other diseases around the world
2. Motor-vehicle safety
3. Safer workplaces
4. Control of infectious diseases
5. Decline in deaths from coronary heart disease and stroke
6. Safer and healthier foods
7. Healthier mothers and babies
8. Family planning
9. Fluoridation of drinking water
10. Recognition of tobacco use as a health hazard

Public health is founded on the efforts of a society to protect, promote, and restore the health of its citizens. Public health programs and services emphasize the prevention of disease and administration of health needs to the population as an entity, versus the study and treatment of a single patient, as is found in the discipline of medicine. Today, *public health* is defined as “the science and the art of preventing disease, prolonging life, and promoting physical health and mental health and efficiency through organized community efforts . . . and the development of the social machinery to ensure to every individual in the community a standard of living adequate for

the maintenance of health.”² The mission of public health is to fulfill society’s desire to create conditions so that people can be healthy. **Public health** is divided into the staple **pillars of assessment, policy development, and assurance**.³ All three of these pillars are interdependent and cyclical. Two functions address the issues of **assessment**: (1) **monitor health** and (2) **diagnose and investigate**. Under **policy development** are the functions (1) **inform, educate, empower**; (2) **mobilize community partnerships**; and (3) **develop policies**. The following functions define **assurance**: (1) **link to and/or provide care**, (2) **ensure a competent workforce**, and (3) **evaluate**.³

Like traditional programs in public health, ranging from maternal and reproductive health to injury control and prevention, the public health response to disasters also fulfills the same basic tenets of assessment, policy development, and assurance. This chapter introduces the reader to how public health integrates into disaster preparedness and response systems by highlighting some specific subjects relevant to those tenets. It will cover topics like the public health disaster response cycle, policies in disaster response, the provision of disaster medical services, as well as worker safety and epidemiological/data issues (Figure 1-1).

PUBLIC HEALTH RESPONSE CYCLE

Mitigation is the process of recognizing risks and vulnerabilities and then working to both reduce the vulnerability and strengthen society’s ability to withstand an unstoppable event or to reduce the effects from a disaster. Public health seeks to mitigate hazards such as explosions, chemical exposures, natural disasters like floods and earthquakes, and infectious disease, as well as reducing vulnerabilities of the infrastructure such as weak assets, resources, personnel, and science. One form of mitigation may be hardening structures against blast, but also can be the placement of surveillance systems to increase early detection of infectious diseases in a hospital setting, for example. Today, these systems, as well as reporting parameters, are being put into place across the country to both recognize and protect populations from a bioterrorism event. Early warning offers the benefit of a rapid response and reduction in morbidity and mortality.

Preparedness is the process of developing a formal program of response. Preparedness has many components, including: training and staff development; identification and classification of public health resources including personnel, supplies, and facilities; development of standard operating procedures (SOPs), emergency response plans, and communications plans; and pre-placement of key supplies and protective equipment. This phase should also include the participation in tabletop and functional exercises. Public health personnel must be integrated and participate with other response agencies during drills and exercises to better familiarize each stakeholder with their respective roles and abilities. In addition, this is the phase in which public health agencies would develop interagency agreements, memoranda of understanding (MOUs), and external support contracts.

The Centers for Disease Control and Prevention (CDC) is one reference source where planners can obtain basic guidelines for disaster preparedness. These include:

1. Form mutual-aid agreements and close relationships with local, regional, state, and federal partners.
2. Conduct a hazard and risk assessment.
3. Conduct a capacity assessment, identifying resources in your system.
4. Obtain those identified resources and surge capacity.
5. Develop plans consistent with other response organizations in your community.
6. Develop surveillance, registries, and data archiving systems.
7. Plan for public affairs and risk communication.
8. Ensure personnel are trained and certified to use personal protective equipment and other health practices.
9. Orientation for volunteers and personnel on procedures, guidelines, and command and management systems.
10. Participate in and conduct exercises.
11. Participate in after-action reviews of exercises and incidents.⁴

Response is the phase in which each agency and section with responsibility to respond activates its emer-

gency response plan to the specific threat or situation and can incorporate local, regional, and federal response. For example, in response to a biologic or chemical terrorist event, public health agencies would respond by conducting site surveys, recommending public safety measures and communicating risk, providing epidemiologic investigations, providing medical treatment of prophylaxis for those exposed, and initiating disease prevention and environmental decontamination measures.⁵

RECOVERY

Public health agencies must identify what resources may be available to assist in restoring the operation as well as address other physically and emotionally affected populations. Public health recovery operations are multidisciplinary and involve multiple sectors of society (law enforcement, military, public policy, public works), and they vary depending on the extent of the disaster's societal impact. Furthermore, recovery efforts comprise several components, some of which are Search and Rescue (SAR) in the case of an earthquake, bombing, or landslide; reinstatement of medical services if clinics and hospitals are destroyed; and establishment of corrupted lifelines like sanitation, electricity, and water. Those affected by the horrendous Tsunami disaster—that killed hundreds of thousands in Indonesia, Thailand, India, and so many other nations—demonstrated the international public health relief operation: an extreme example of multilateral, global relief spanning commercial and government sectors. The recovery from this disaster is ongoing and likely will last several years.

DISASTER POLICY

For weeks after the 2004 tsunami, survivors on makeshift rafts were miraculously saved and brought back to shore. At the same time, the United States faced its own disasters. Thirteen people were trapped and 6 died from

LOCAL PUBLIC HEALTH RESPONSE TO THE WORST TERRORIST ATTACK IN U.S. HISTORY

On Sept. 11, 2001, two commercial jets that were hijacked by terrorists crashed into the two towers of the World Trade Center in New York City. Within 90 minutes, both 110-story towers had collapsed. The New York State Department of Health (NYS DOH) had pre-established Emergency Operations Center committees that came together and began working within 30 minutes of the attack. NYS DOH nursing staff assisted in triaging and treating injured persons at an emergency triage center. In collaboration with the American Red Cross, the DOH also provided nursing staff for emergency shelters that housed displaced residents. Within the disaster site and surrounding commu-

nity, DOH performed environmental monitoring. With losses in power and water as well as having tons of airborne contaminants in the area, DOH had its hands full with monitoring both the general public and emergency responders in addition to performing its daily activities. The DOH regularly sent faxes, e-mail alerts, and press releases containing urgent public health information and/or concerns to local hospitals and physicians. The DOH designed and implemented a rescue and recovery worker-safety plan. Additionally, the DOH initiated four disease and injury surveillance systems after the disaster, with assistance from the CDC.

mudslides in La Conchita, California; and a train disaster in Graniteville, South Carolina released concentrated chlorine fumes, leading to 9 deaths and 250 hospitalizations. Finally, in the fall of 2005 Hurricane Katrina devastated the Gulf coast of the United States, resulting in the flooding and complete evacuation of New Orleans. Although these disasters are not on the same scale in terms of death, injury, social loss, and destruction as the tsunami, they still maintain criteria that classify them as disasters.

What determines whether an event is treated as a federal disaster? Locally, only the governor of a state or his or her appointee can declare a federal disaster through coordination with the Federal Emergency Management Agency (FEMA) regional director through the Federal Response Plan (FRP), under the Stafford Disaster Relief and Emergency Assistance Act.⁷ The FRP under the Stafford Act is an interagency plan that outlines the delivery of federal resources to state and local governments when a disaster overwhelms the region's ability to respond self-sufficiently. When state or local resources are insufficient to respond to and recover from a disaster, the presidential declaration sets forth long-term federal disaster recovery programs.⁷ The Stafford Disaster Relief and Emergency Assistance Act's definition of a major disaster is stated in the following⁷:

Any natural catastrophe (including any hurricane, tornado, storm, high water, wind-driven water, tidal wave, tsunami, earthquake, volcanic eruption, landslide, mudslide, snowstorm, or drought), or, regardless of cause, any fire, flood, or explosion in any part of the United States, which in the determination of the President causes damage of sufficient severity and magnitude to warrant major disaster assistance under this Act to supplement the efforts and available resources of states, local governments, and disaster relief organizations in alleviating the damage, loss, hardship, or suffering caused thereby.

A major disaster declaration makes available all federal disaster relief assistance to affected communities. This can include repair, replacement, and reconstruction of public and nonprofit facilities; cash grants for personal victim needs; temporary housing **vouchers** or replacement accommodations; and unemployment assistance.⁸

Following the Sept. 11 attacks in 2001, the President declared the Homeland Security Presidential Directive (HSPD)-5, in which he called for the development of a new National Response Plan (NRP) "to align Federal coordination structures, capabilities, and resources into a unified, all-discipline, and all-hazards approach to domestic incident management."⁶ The premise of this robust plan is to standardize and make seamless the manner of operations for all levels of disaster response from local to federal, as well as private and public, agencies. The NRP will establish a national framework, standardizing aspects of coordination, communications, incident management, and information sharing, as well as streamline disaster policy directives and protocols. Upon full implementation of the NRP, it will supersede the Initial National Response Plan (INRP), the Federal Response Plan (FRP), the U.S. Governmental Interagency Domestic Terrorism Concept of Operations Plan (CONPLAN), and Federal Radiological Emergency Response Plan (FRERP).

The NRP also provides for guidance to initiate long-term community recovery and mitigation.⁶

When the NRP is fully implemented, the Secretary of Homeland Security will declare "incidents of national significance." The drafted NRP in December 2004 outlined four criteria that constitute an "Incident of National Significance":

1. A federal department or agency acting under its own authority has requested the assistance of the Secretary of Homeland Security.
2. State and local resources and authorities are overwhelmed and federal assistance has been requested by the state and local authorities.
3. More than one federal department or agency has become substantially involved in responding to an incident.
4. The Secretary of Homeland Security has been directed to assume responsibility for managing a domestic incident by the President.⁶

One specific support function most applicable to public health is called the Emergency Support Function #8—Public Health and Medical Services, or ESF-8. ESF-8 provides supplemental assistance to State, local, and tribal governments in identifying and meeting the public health and medical needs of victims of an Incident of National Significance. This support is categorized in the following core functional areas:

- Assessment of public health/medical needs (including behavioral health)
- Public health surveillance
- Medical care personnel, and
- Medical equipment and supplies.⁶

The NRP **stipulates** that the coordinator and the primary agency is the Department of Health and Human Services.

OPERATING PUBLIC HEALTH

The American Public Health Association (APHA) provides principles to guide public health's response toward terrorism.¹¹ From a list of 12 principles, the following seven are of specific interest to this chapter:

1. Strengthen the **public health infrastructure** (which includes workforce, laboratory, and information systems) and other components of the public health system (including education, research, and the faith community) to increase the ability to identify, respond to, and prevent problems of public health importance, including the health aspects of terrorist attacks.
2. Ensure the availability of and accessibility to **health care, including medications and vaccines**, for individuals exposed, infected, made ill, or injured in terrorist attacks.
3. **Educate and inform health professionals** and the public to better identify, respond to, and prevent the health consequences of terrorism and promote the visibility and availability of health professionals in the communities that they serve.

4. Address **mental health needs** of populations that are directly or indirectly affected by terrorism.
5. Ensure the protection of the **environment**, food and water supply, and health and safety of **rescue and recovery workers**.
6. Ensure clarification of the roles, relationships, and responsibilities among public health agencies, **law enforcement, and first responders**.
7. Build and sustain the public health capacity to develop **systems to collect data** about the health and mental health consequences of terrorism and other disasters on victims, responders, and communities and develop uniform definitions and standardized data classifications systems of death and injury resulting from terrorism and other disasters.

This chapter introduces basic concepts, discussions, and recommendations regarding the following key issues arising from these selected APHA principles: (1) public health infrastructure; (2) medical services, including the distribution of drugs and supplies; (3) education, training, and communications; (4) environmental health and precautions; (5) mental health; (6) worker safety and first responders; and (7) data collection and analysis.

PUBLIC HEALTH INFRASTRUCTURE

Formal public health programs in the United States have existed for well over 200 years. For example, the origins of the U.S. Public Health Service (USPHS) (initially known as the Marine Hospital Service) may be traced to the passage of an act in 1798 that provided for the care and relief of sick and injured merchant seamen. After its inception and over the next 200 years, the Marine Hospital Service was restructured to provide a much wider variety of essential services.

Today's USPHS is recognized worldwide. Working alongside its other federal partners and state agencies, including the DHHS (and its agencies, such as the CDC, the Food and Drug Administration [FDA]), and the U.S. Department of Agriculture (USDA), the USPHS continues to be an active partner in the nationwide system of public health at the federal level and to influence public health on a national scale. The USPHS has, until recently, provided active support and direction to the NDMS (now directly under FEMA). The USPHS continues to respond to and support operations as a partner of NDMS, providing expertise in several areas.

The U.S. public health system encompasses a broad integration of commercial, public, government, and non-government entities. It is as diverse as the very population it serves. It includes government public health agencies operating on federal, regional, state, and local levels; healthcare delivery infrastructure, such as hospitals and clinics; public health and health science academic institutions; community entities, such as schools, organizations, and religious congregations; commercial businesses; and the media.³ Public health is also augmented by its partnerships and increasing collaboration with expert military health institutions, such as the U.S. Army Medical Research Institute of Infectious Diseases

(USAMRIID) and other defense agencies; national institutions such as the National Institute for Allergy and Infectious Disease (NIAID), under the National Institutes of Health (NIH); law enforcement and emergency responder communities on federal (Federal Bureau of Investigation) and local levels; and the medicolegal community, which is composed of national medical examiners offices and forensic scientists.

Public health response is not centralized (for better or worse) and incorporates multiple government agencies, ranging from those involved in research and development (e.g., Bioshield at DHHS) to victim assistance (e.g., NDMS at DHS). Bioterrorist response, for example, involves an enormous breadth of players and their respective functions.⁹ The DHHS alone elicits responses from its agencies: the Agency for Healthcare Research and Quality (AHRQ), CDC, FDA, NIH, and Office of Emergency Preparedness (OEP). Other departments that participate in public health include the USDA, including its Animal and Plant Health Inspection Service (APHIS), Agricultural Research Service (ARS), Food Safety Inspection Service (FSIS), and Office of Crisis Planning and Management (OCPM); agencies under the Department of Commerce (DOC), including the National Institute of Standards and Technology (NIST); agencies under the DOD, including the Defense Advanced Research Projects Agency (DARPA), Joint Task Force for Civil Support (JTFCFS), National Guard, and U.S. Army; the Department of Energy (DOE); the Department of Justice (DOJ), including the Federal Bureau of Investigation (FBI) and the Office of Justice Programs (OJP); agencies under the Department of the Transportation (DOT), including the U.S. Coast Guard (USCG); agencies under the Department of Treasury (Treasury), including the U.S. Secret Service (USSS); the VA; the Environmental Protection Agency (EPA); and FEMA.⁹

Different agencies function to deliver services to varying target audiences. For example, the target audiences of the CDC are state and local health agencies. In terms of activities, the CDC provides grants, technical support, and performance standards to support preparedness and response planning for bioterrorism; chemical and radiological incidents; natural disasters; and terrorist incidents, such as explosions, that may yield significant physical trauma.⁹ The OEP enhances medical response capabilities, such as early identification of a biologic incident, mass prophylaxis, mass casualty care, and mass fatality management.⁹ Its target audiences are local jurisdictions, including fire and police departments, emergency medical services (EMS), hospitals, and public health agencies.⁹ The DOJ helps states develop strategic plans and funds training, the obtaining of equipment, and the planning of drills and exercises for fire, law enforcement, emergency medical and hazardous response (HazMat) teams, hospitals, and public health departments.⁹ FEMA supports state emergency management agencies by providing grant assistance to sustain local-consequence management planning, training, and exercises for all disasters, including biological incidents.⁹ For example, FEMA, with the U.S. Army, conducts the Chemical Stockpile Emergency Preparedness Program (CSEPP) and the Radiological Emergency Preparedness (REP)

program.¹² The goal of CSEPP is to improve preparedness in the event of an accident involving U.S. stockpiles of obsolete chemical munitions.¹² The REP carries out exercises to ensure that residents living around nuclear power plants are safe and prepared in case of a disaster.

In the event of a disaster, responders on the front line will be public health officials, health care workers (physicians, nurses, other medical professionals), public works personnel, firefighters, EMS personnel, and law enforcement officers.⁹ The core public health component will involve local public health departments, which have been described as “. . . the critical components of the public health system that directly deliver public health services to citizens.”¹³ A public health department is an administrative and/or service unit of local or state government that is staffed with a median of 20 people, varying between 1 and sometimes more than 20,000, with an average of 72 full-time workers.¹³ Local public health departments provide services ranging from immunizations to food and milk inspections.¹³ Most departments conduct childhood and adult immunizations, communicable disease control practices, epidemiology and surveillance, community assessment, and sexually transmitted disease counseling.¹³ Some others have injury control programs, solid waste management, and comprehensive primary care services.¹³

Health departments will likely not be the lead agency in a disaster and therefore must work closely with other organizations and fall into the incident command during an emergency.⁹ Health departments and all emergency response agencies should establish, in the planning phase, mutual aid agreements and close working relationships with key partners in their region.

Partners include emergency management agencies (EMAs); EMS; medical and behavioral healthcare providers; fire departments; law enforcement; local emergency planning committees; state, regional, and tribal public health response coordinators; neighboring health jurisdictions; humanitarian and volunteer organizations; private businesses; and academic institutions, such as schools of public health and medicine.⁹ For example, between August and September 2004, four hurricanes (Charley, Frances, Ivan, and Jeanne) ripped through Florida, ravaging hundreds of thousands of homes; displacing huge populations; and prompting the aid of 5000 FEMA workers in 15 states and 3800 National Guard members who provided security, directed traffic, and distributed supplies.¹⁴ Additionally, more than 140,000 volunteers spanning state and national volunteer organizations, such as the Red Cross and faith-based groups, arrived in Florida to lend help, ranging from preparing meals to removing trees.¹⁵ Further, the U.S. Public Health Services works alongside its other federal partners and state agencies, including the DHHS and its agencies, the CDC, and the FDA, as well as the USDA. They continue to be an active partner in the nationwide system of public health at the federal level in order to influence public health on a national scale. The USPHS has until recently provided active support and direction to the National Disaster Medical System (now directly under FEMA) in the Department of Homeland Security. They continue to respond and sup-

port operations as a partner of NDMS, providing expertise in several areas.

Medical Services

A biologic attack could result in the infection thousands of people without any indication in the first few hours of how many people are infected.¹⁶ For example, one hypothetical scenario depicted a national and global spread of smallpox, resulting in 15,000 cases and 2000 deaths.¹⁷ It is therefore recommended to provide mass prophylaxis to the population—the use of antibiotics being the primary key to survival for most people.¹⁶ Some believe that vaccines are not the first line of defense against biological threats but can be used for control of a smallpox epidemic, prophylaxis against anthrax in combination with antibiotics, control of global pandemic infections, and pre-exposure prophylaxis for high-risk workers in laboratory and health care environments.¹⁸

Because most public health departments, hospitals, and local institutions lack the amount of drugs needed for a national emergency, federal medical resources are available through the Strategic National Stockpile (SNS), formerly named the National Pharmaceutical Stockpile (NPS). After institution of the Homeland Security Act of 2002, the DHS and CDC began to jointly manage the SNS, with the DHS defining the goals and performance requirements of the program and being responsible for administering the actual deployment of the 12-hour push package.¹⁹ The cache of medical supplies includes antibiotics, chemical antidotes, antitoxins, life support medications, intravenous administration and airway maintenance supplies, and medical/surgical items that can be delivered in the event of a national emergency within 12 hours to strategically designated warehouses across the United States and its territories.¹⁹ The SNS is not meant to be a first response tool but rather to augment and restock existing state and local health agencies' medical supplies. The SNS program conducts quarterly quality assurance checks, rotates materials, performs a full annual inventory of all package items, and regularly inspects environmental conditions, security, and overall package maintenance.¹⁹ Deployment of the SNS is made when the state governor's office directly requests assets from the CDC or DHS.¹⁹

Once the SNS cache has been delivered, several key steps must be taken to effectively use it: officially receive the supplies and unload them; have adequate personnel for packaging, distributing, dispensing, tracking, and storing the supplies; have the local public health department assign dosages; and provide communication and security.¹⁶

There are additional public health issues beyond these logistics that should be taken into account when distributing mass prophylaxis to the public. They include dividing the population into groups who require medication first, a step that is politically sensitive and should be decided before a biologic attack happens.¹⁶ Also, public health personnel should be ready to distribute clear agent-specific and drug information, to make available multilingual staff and handouts, to handle the needs of special populations, to provide personal protective equipment

(PPE) for people at staffing and dispensing centers, and to provide security in case of crowd panic.¹⁶

Disasters cause various patterns of injury and disease, ranging from blast injuries by a terrorist bombing to ventilatory failure from the chemical release of a nerve agent. As a result, responses significantly vary in terms of how widespread the response is (local to international), which personnel are used to respond, the duration of the response, and what medical management must be used to treat those affected or exposed.

For example, some infectious diseases require a larger response, for which the help of national and sometimes international partners and resources is needed to identify the agent, conduct surveillance, report, and treat the range of people who may be infected. Such responses may vary in location and size. However, natural disasters, such as hurricanes, call for a different type of medical response altogether, in which medical problems seem to arise out of environmental hazards resulting from the natural disaster's aftermath. For instance, injuries and deaths occur because victims fail to evacuate and take shelter, do not take precautions in securing property, and do not follow guidelines for food and water safety or injury prevention during the recovery phase.²⁰ Injuries from a hurricane can result from near-drowning; electrocution; lacerations from flying debris; blunt trauma or bone fractures from falling trees and other heavy objects; stress-related disorders; heart attacks; gastrointestinal, respiratory, vector-borne, and skin diseases; toxic poisoning; fires; bites from displaced wild animals, such as animals and snakes; and even improper use of mechanical equipment, such as chain saws and power tools.²⁰

Chemical and radiological incidents have more specific medical issues, including the recognition of patterns of injury, prophylaxis, and antidotes. Managing a volume of exposed patients in a limited healthcare environment can be challenging and can include issues of decontamination; on-site prehospital management; transportation; the use of PPE; and treatment of patterns of injury specifically associated with chemical and radiological sequelae, such as skin lesions, blisters and burns, nervous system disorders, inhalational injuries, and acute radiation syndrome. Some disasters fall into less specific points for medical management due to the nature of the event.

Consider the blackout on Aug. 14, 2003, in the Northeastern United States and Southeastern Canada (Ottawa and Toronto) that affected 50 million people and a total of 240,00 square kilometers in areas including New York, New Jersey, Vermont, Michigan, Ohio, Pennsylvania, Connecticut, and Massachusetts.²¹ The blackout, suspected to have been caused by a downed 340,000-volt power grid, caused the shutdown of 21 power plants across the nation.²² The blackout affected all electrical functions, shutting down computers, trapping passengers in high-rise elevators, stalling subways, and disrupting airport control and landing procedures, hospital activities, food refrigeration, traffic operations, and most channels of communication. Facilities with backup generators were able to continue operations, but only sparingly. In the United States, three people died as

a result of the blackout and one firefighter was injured. In Ottawa, a teenager died from fire-related injuries and another person died after being hit by a car. In New York during the 30-hour period of no electricity, 3000 fires were reported, mainly from people using candles, and EMS personnel responded to 80,000 calls to 911, double the average.²²

On the other hand, finite, sudden disasters causing immediate injury and mortality (such as terrorist bombings, transportation disasters, and building collapses) require a more robust response capacity at a local and perhaps regional level. This differs from the national and sometimes international assistance required after large-scale natural disasters that affect vast regions of terrain, as was seen in the case of the 2004 tsunami disaster, as well as in several instances of floods, hurricanes, and even complex humanitarian emergencies overseas. In the case of an explosion, trauma systems must be equipped and ready to accept incoming patients, manage the bulk of patients with minor wounds who will flood the nearest hospital, and prepare for possibly unexpected rates of casualty flow. Physicians should be prepared to treat hundreds of trauma patients, which may be complicated by loss of utilities, difficulty in reaching hospitals, or possible damage to hospital facilities.²³ The physically injured from high-energy disasters, such as earthquakes, tornadoes, or explosions, will most likely be treated at regional trauma centers for severe injuries. In the United States, there are 600 regional trauma centers.²⁴ They coordinate EMS, including paramedics and air medical transport. A regional trauma center is composed of paramedics and emergency medical technicians (EMTs) who transport injured victims to trauma teams that include a trauma surgeon, emergency physician, several trauma nurses, and specialized personnel. Up to 16 physicians in various specialties, from neurosurgery to obstetrics, comprise a trauma team ready to receive injured patients in the operating room and critical care unit.²⁴

For disease outbreaks, the provision of medical services and public health capabilities is considerably great and involves a large network of local to sometimes international response. When severe acute respiratory syndrome (SARS) made its way onto the global front as a highly threatening disease in November 2002, it crippled the Asian healthcare system and brought to light serious questions about the U.S. public health system's ability to respond to a similar crisis at home. SARS had the greatest impact on Asian countries, with 7782 cases and 729 deaths, challenging Asian healthcare systems, adversely affecting Asian economies, and testing the effectiveness of international health codes.²⁵ SARS is part of the coronavirus family. Within 2 to 10 days after infection, the affected person can develop symptoms including cough, fever, and body aches that are indiscriminate from other respiratory illnesses, appearing as an atypical pneumonia.²⁵ The fatality rate from SARS is 11% and can be greater than 50% for people older than 65.²⁵ SARS is a person-to-person transmitted disease that is acquired primarily through direct and indirect contact with respiratory secretions and/or contaminated objects.

An international outbreak of SARS took place from February through deep into the spring of 2003. When an infected physician who treated SARS patients in China stayed at a hotel in Hong Kong on travel, those who resided at the hotel acquired the disease and subsequently departed to Vietnam, Singapore, and Toronto, Canada, seeding secondary outbreaks.²⁵ Cases spread from Asia to 26 countries, and at its peak in May 2003, hundreds of cases of SARS were being reported each week.

To prevent and control the spread of SARS, public health efforts of case identification and contact tracing, transmission control, and exposure management were utilized. *Case identification and contact tracing* is “defining what symptoms, laboratory results, and medical histories constitute a positive case in a patient and tracing and tracking individuals who may have been exposed to these patients.”²⁵ *Transmission control* is “controlling the transmission of disease-producing microorganisms through use of proper hand hygiene and personal protective equipment, such as masks, gowns, and gloves.”²⁵ *Exposure management* separates those infected from noninfected individuals through the use of quarantine, which restricts movement of those who are not ill but were exposed to the disease agent and are potentially infectious.²⁵

EDUCATION, TRAINING, AND COMMUNICATIONS

Tabletop exercises are one form of disaster planning education. Participants of a tabletop exercise are broad and may include government officials (mayors, city council members, risk manager), public works/utilities personnel (water superintendent, gas company representative), law enforcement (police chief, sheriff), community services (Red Cross representative), emergency management (emergency program manager, National Guard representative), fire department representatives (fire chief, dispatcher), emergency medical/health personnel (emergency medical coordinator, public health official), and public information officers.¹² The tabletop exercise, which commonly includes senior-level officials, prompts participants to discuss how their respective agencies or units might react to a specific set of scenarios, emphasizing higher-level policy and procedural issues.¹² Unlike full-scale exercises or field exercise drills, such as a hospital disaster simulation in which operations are evaluated on scene and equipment is deployed, tabletop exercises do not involve management of equipment or personnel, but are rather classroom-type exercises held in a classroom setting.¹²

Full-scale exercises engage tactics, techniques, and procedures that could be used in an actual incident and are designed to be realistic.¹² In May 2000, May 2003, and most recently May 2005, FEMA led three exercises called the Top Officials (TOPOFF1, TOPOFF2, and TOPOFF3), which were large-scale, “no-notice” field drills involving federal, state, and local agencies. TOPOFF1 in

2000 was jointly led by FEMA and DOJ and was conducted in three cities: a biological weapons incident in Denver, Colo., a chemical incident in Portsmouth, N.H., and a mass casualty radiological incident in the Washington, D.C. region.¹² In 2003, the TOPOFF2 4-day drill involved a Radiological Dispersal Device (RDD), or “dirty bomb,” release in Seattle, Washington, and a biologic incident involving *Yersinia pestis*, or Pneumonic Plague, in Chicago.²⁶ TOPOFF3 was the largest U.S. counter-terrorism exercise to date. It exceeded 10,000 players, and involved 275 federal, state, local, and private organizations, as well as international partners Canada and the United Kingdom, with 13 countries sending representative observers. The exercise simulated a chemical release attack in New London, Connecticut, and a biologic attack in New Jersey.

Physicians and other healthcare providers are often-times on the front line when detecting a disease outbreak and play a primary role in early detection of the disease:

“Health-care providers should be alert to illness patterns and diagnostic clues that might indicate an unusual infectious disease outbreak associated with intentional release of a biologic agent and should report any clusters or findings to their local or state health department. . . .”^{23,27}

Physicians and other healthcare providers are recommended to maintain a high level of suspicion for rare disease, ascertain thorough patient histories, and evaluate occupational and environmental exposures.²⁸ The CDC indicates the following three signs of a possible intentional biological release, emphasizing physicians should stay alert for the following²⁷:

1. An unusual temporal or geographic clustering of illness (e.g., persons who attended the same public event or gathering) or patients presenting with clinical signs and symptoms that suggest an infectious disease outbreak
2. An unusual age distribution for common diseases
3. A large number of cases of acute flaccid paralysis with prominent bulbar palsies, suggestive of a release of *botulinum* toxin

Most of the knowledge base and skills needed to treat patients after a terrorist or nonterrorist disaster involves an extension of everyday tools that physicians already possess.²³ What is necessary is to “fill in the blanks,” as proposed by the American Medical Association.²³ This may include symptoms to become familiar with for early recognition of an unusual infection, guidelines to manage chemical- and radiation-contaminated patients, and protocols to triage and treat acute trauma patients after an explosion. To this extent, professional organizations and societies have become involved in the development of education on disasters and terrorism, and a great degree of seminars, distance learning programs, books, periodicals, web sites, and self-study material have been organized to educate healthcare providers.²³ Such steps have been taken not only in physician communities but also in nursing, physician assistant, and technician communities through the same routes of education and

training. Notable experts have commented that public health Internet sites, such as the CDC's bioterrorism web page, have kept the public informed and have helped keep physicians aware of the latest developments and recommendations in bioterrorism.²⁸

In times of disaster, there is an essential need to communicate certain health matters to the public. Public health officials often gain and transmit information from a range of various sectors²⁰:

- The public (most importantly)
- Hospitals and their emergency departments
- Community providers
- Social service agencies
- First responders, such as fire, police, and EMS
- National Guard representatives
- Local and regional laboratories
- Policy makers, such as public officials, mayors, and governors
- Traditional partners, including the American Red Cross and the public works system

Through communication with the media, public health agencies can set up a network, delivering health reports regularly so that the general public can receive important updates and educational messages.²⁰ These messages must be factual and credible to the public and delivered through advance protocols, in which a single public information officer has been appointed to deliver the information.²⁰ Some likely public health information might include food and water safety, injury prevention measures, and warnings that, for example, increase timely evacuation from hurricanes and shelter against tornadoes.²⁰ Also, information should contain facts about the expected hazards (natural, man-made, or technological disaster), safety precautions, and requirements for evacuation or shelter-in-place.²⁰ All messages should be clear (messages in writing should be understood and bilingual, if needed) and concise; technical information should be translated into simple language for a general audience. Importantly, the sender of information should verify that the transmitted message has been received and understood by the intended audience. When the public heeds the actions and recommendations made by public health officials, those messages have been adequately delivered to the audiences.²⁰ Experts emphasize that warning messages should not be withheld until the last minute. This has been documented to happen out of fear that panic will overwhelm the public and lead to more deaths and injuries than the actual disaster.²⁰

Internally among public health systems and partners, secure and redundant lines of communication should be set up during a disaster. These include computers with a CD drive, e-mail capability, continuous online Internet access, and security software to protect sensitive data from intruders.²⁰ Fixed facilities such as hospitals and health departments should have a standby source of power to operate electrical and communication systems in case a disaster strikes the main source.²⁰ Communication equipment that has been used for public health response includes radio equipment, such as two-way radios, pagers, broadcast radios, televisions, and satellites; wire lines, such as telephones, facsimile machines,

and computer modems; and a combination of both radio and wire lines, including cellular and satellite telephones.²⁰ However, it is important to realize that in times of disaster, routine communications like these may not be readily available, especially to the public and private sectors. Such was the case in the London Bombings on July 7, 2005, when private businesses found it nearly impossible to access e-mails or make mobile phone calls, as cellular networks were congested from a surge in traffic.

ENVIRONMENTAL HEALTH AND PRECAUTIONS

Environmental health precautions after a disaster will decrease illness, injury, and death. The risks of infection increase in the days after a disaster due to disrupted water supplies and the problem of sanitation control. These include maintaining water and food safety, proper sanitation and waste disposal, and the control of vector populations.²⁰ The environmental health priorities of most health departments include the following²⁹:

1. Ensuring an adequate supply of safe drinking water
2. Providing food protection measures
3. Ensuring basic sanitation services
4. Promoting personal hygiene
5. Assisting the efforts of first responders by providing health risk consultations or advising on exposure pathways
6. Providing information to emergency managers to help assess the scale of the emergency to ensure an effective response

Landesman²⁰ recommends a three-tiered approach to reduce exposure to environmental hazards:

1. Measures of control that involve preventing the hazard in question from being released or occurring; controlling its transport; and keeping people from being exposed, such as cleaning, treating, and collecting clean water
2. Establishing multiple barriers, meaning setting up redundant obstacles to separate unsanitary conditions from human contact that can sometimes be a matter of public works engineering
3. Distance between hazards and populations

Quantitative analyses must be used in a survey fashion to identify existing disposal facilities and procedures in a community; to determine how to deliver sanitation coverage; and to distribute safe drinking water and establish water consumption rates. Consumption of and contact with contaminated water supplies from run-off sewage and disrupted sewage systems can lead to fecal-oral diseases such as cholera, typhoid fever, hepatitis A, and shigella.²⁰ Public health notices to boil water, avoid certain foods that may have spoiled, and that provide locations of potable water are key to environmental safety. Improper food storage, for example, is often associated with *Bacillus cereus*, *Clostridium perfringens*, *Salmonella*, *Staphylococcus*

aureus, and group A *Streptococcus*.²⁰ Sufficient shelter must take into account weather conditions during the disaster, such as warm or cool climates. Insufficient housing can expose people to environmental conditions that make them susceptible to frostbite, hypothermia, heat stroke, and dehydration.²⁰ Especially important to take into account are educational messages and warnings about carbon monoxide poisoning and untrained use of mechanical power generators. Pest control to reduce infestation of rat and mosquito populations is also important.

MENTAL HEALTH

Several studies describe, characterize, and propose interventions for mental health issues encountered after a disaster. Experts note the wide range of questionnaires, surveys, interviews, and psychiatric classification systems used to document postdisaster psychological sequelae and note the difficulty in cross-comparison and generalization of these findings toward many disasters.²⁹ Although the disaster community agrees that effects of mental health require more investigation, they also agree that “the worst scars in disasters are psychological and social scars.”³⁰ Mental health issues stemming from disasters are becoming increasingly integrated into postdisaster assessment, with more emphasis on mental health being an urgent aspect of public health relief.

The mental health community stresses that providers and disaster relief personnel need to have a meaningful understanding of the psychological and social needs of victims in a disaster.³⁰ Disasters can provoke specific emotional reactions that take on a variety of different psychological responses, affecting primary victims (those directly involved in the disaster) and secondary victims (such as relatives, co-workers, and schoolmates). Other people who can experience mental health issues include onlookers, rescuers, body handlers, health personnel, evacuees, and refugees.³⁰ It is important to realize that most adults and children will experience normal stress reactions for several days after a disaster (Box 2-1).³¹ One should note that normal stress reactions can also spawn personal introspection, growth, and resilience.

The three forms of mental health problems that may follow a disaster are acute stress reactions, posttraumatic stress disorders (PTSDs), and adjustment disorders or enduring personality change.³⁰ Acute reactions are characterized by absence of emotion; lack of response to external stimuli; total inhibition or outward activity and random movements; persons being stunned or shocked; and psychosomatic symptoms such as tremor, palpitations, hyperventilation, nausea, and vomiting.³⁰ PTSD is defined as³²:

An anxiety disorder (and diagnostic construct used in the *Diagnostic and Statistical Manual of Mental Disorders-IV*) that can develop after exposure to a terrifying event, or ordeal in which grave physical harm occurred or was threatened. The criteria for PTSD require:

BOX 2-1 NORMAL STRESS REACTIONS AFTER A DISASTER

Temporary emotional reactions
 Shock
 Fear
 Grief
 Anger
 Hopelessness
 Emotional numbness
 Cognitive reactions
 Confusion
 Disorientation
 Worry
 Memory loss
 Unwanted memories
 Physical reactions
 Tension
 Fatigue
 Difficulty with sleeping
 Change in appetite and sex drive
 Interpersonal reactions to relationships at work and school or within a marriage or family (these may be characterized by distrust, irritability, isolation, judgmental attitude, and being distant)

- A. Exposure to a traumatic event
- B. Reexperiencing of the event
- C. Persistent avoidance of stimuli associated with the trauma
- D. Persistent increased arousal
- E. Duration of B, C, D of more than one month
- F. Clinically significant distress or impairment

One of three survivors experiences severe stress that can lead to PTSD, anxiety disorders, or depression. Severe reactions possibly leading to PTSD include dissociation, intrusive reexperiencing (nightmares), extreme attempts to avoid disturbing memories (substance use), extreme emotional numbing, hyperarousal (panic attacks, rage), severe anxiety (extreme helplessness, compulsions, or obsessions), and severe depression. The mental health ramifications are possibly greater for those who witness or are involved with certain experiences from a disaster. Some examples include loss of loved ones; life-threatening danger or physical harm (especially to children); exposure to gruesome death, bodily injury, or dead and maimed bodies; extreme environmental or human violence and destruction; and loss of home.³¹ Inherently, specific individuals might have a typically higher risk of severe stress and lasting PTSD, such as those with a history of exposure to other traumas, chronic medical illness and psychological disorders, chronic poverty, and recent emotional strain.³¹ On the other hand, the National Center for PTSD states that some factors might be protective, including social support, higher income and education, successful mastery of past disasters and traumatic events, reduction of exposure to trauma, and provision of regular and factual information about the emergency.

At a recent national workshop on mental health and disasters, experts recommended some early intervention actions.³² *Early intervention* is defined as³²:

The provision of psychological help to victims and survivors within the first month after a critical incident, traumatic event, emergency, or disaster aimed at reducing the severity or duration of event-related distress. For mental health service providers, this may involve psychological first aid, needs assessment, consultation, fostering resilience and natural supports, and triage, as well as psychological and medical treatment.

Interventions include provision of the following:

1. Basic needs
2. Psychological first aid
3. Needs assessment
4. Rescue and recovery environment observation
5. Outreach and information dissemination
6. Technical assistance, consultation, and training
7. Fostering resilience and recovery
8. Triage
9. Treatment

In regard to training, there are specific issues to consider when conducting mental health studies in foreign nations. International authors agree that a definite level of cultural social awareness, support for indigenous and local authorities, multi-integration into capacity and infrastructure rebuilding, understanding of the political dynamic (especially in regions where there is conflict), and assessment of mental health based on scientific and clinical knowledge are imperative from an ethical standpoint and will increase the success of the program.³³

WORKER SAFETY AND FIRST RESPONDERS

In the United States, there are more than 1 million firefighters, with about 75% of those on a volunteer-basis; 556,000 full-time law enforcement personnel at police departments; 291,000 full-time sheriff's personnel; and more than 155,000 nationally registered EMTs.³⁴ These first responders are faced with dual functions: report the first observations about the environment and its risks and simultaneously carry out prehospital tasks. Because the disaster scene is dynamic, with active primary and secondary hazards, emergency responders must characterize the site, where oftentimes the evidence of the causative agent is not yet determined and therefore situational awareness is imperative. This poses emotional, mental, and physical challenges where dangers are likely to arise.

Disasters present emergency responders with primary hazards stemming from the actual causative agent. For example, the release or spillage of a chemical can cause toxic injury, whether it is by a physical asphyxiant (e.g., hypoxemia from inert gas in an enclosed space such as a silo), respiratory irritant (e.g., pulmonary damage and inflammatory response from chlorine or phosgene), or systemic toxicants (e.g., upper airway or alveolar injury or skin or neurological damage from organophosphates, volatile hydrocarbons, or hydrogen cyanide).

Emergency first responders are also jeopardized by secondary risks on site. These hazards can take the shape of several types of environmental risks. For example, rescue personnel can be in danger of confronting hazards from disasters such as riots, explosions and fires, road accidents, farm accidents, factory accidents, and railroad disasters.³⁵ Consider a scenario in which an overturned tanker truck has caused a major road accident; emergency personnel are likely to confront vehicle fires, fuel explosions, the instability of overturned vehicles and truck loads and cargo, the dangers of traffic control and safety, and exposure to release of toxic and dangerous chemicals. Explosions present the first responder with the potential of building collapse, secondary explosions, and toxic smoke release hazards.

First responders are trained to use PPE for a chemical, biological, or radiological event, either intentional or unintentional (as is the case with an industrial accident). Toxic agents can be "invisible" to the senses, and the quantity, type, and time of exposure are not easily known. The National Institute of Justice (NIJ) states: "The purpose of personal protective clothing and equipment is to shield or isolate individuals from the chemical, physical, and biological hazards that may be encountered during hazardous materials operations."³⁶ PPE consists of a wardrobe of clothing and gear that allows the responder to confront and thwart exposure and to function normally. NIJ categorizes PPE into the three following basic categories³⁶:

- Respiratory equipment (e.g., air purifying respirators and supplied air respirators)
- Protective garments (e.g., encapsulated suits, coveralls, and overgarments)
- Other protective apparel (e.g., protective hoods, boots, and gloves)

The NIJ *Guide for the Selection of Personal Protective Equipment for Emergency First Responders* is a good resource for more thorough and detailed information on PPE.³⁶

As the National Institute for Safety and Health points out, large incidents (such as the terrorist attack on the World Trade Center), unlike smaller-scale disasters (such as localized traffic accidents and explosions), pose serious challenges that make it more difficult to protect the responder from injury, illness, and death. Large-scale disasters can do the following³⁷:

- Affect, injure, or kill large numbers of people
- Cover large geographical areas
- Require prolonged response operations
- Involve multiple, highly varied hazards
- Require a wide range of capabilities and resources not routinely maintained by local response organizations
- Attract a sizable influx of independent ("convergent") volunteers and supplies
- Damage vital transportation, communications, and public works infrastructures
- Directly affect the operational capacity of responder organizations

Therefore, responder safety also requires human resource management, in which thoughtful planning can help one to operate in a chaotic, multiagency environment. This includes charting out the chronology of the response (short-term and extended); setting reasonable and efficient work shifts to prevent the exhaustion of personnel; controlling the perimeter and scene to manage convergent volunteers; inventorying and providing access to PPE and resources; and developing highly skilled “disaster safety managers” who possess experience, knowledge, and tactical skills to respond to hazards on site.³⁷ Importantly, and not often considered to be a life-saving function, is the need to manage health and disaster information flooding the scene. This includes the delivery and sharing of critical information among multiple agencies of all types and levels in addition to making sense of overabundant information. This information can include reports of the changing conditions of the disaster scene; data on the number of available workers and their respective health conditions; and standard data on the number, type, and availability of PPE and important resources.³⁸

DATA COLLECTION AND ANALYSIS

Public health detection and analysis follow key functional areas that involve the development and use of surveillance systems, analysis via algorithms and statistical methods, and investigation of disease and injury with great emphasis on critical agents.⁵ Biological agents of highest concern, as categorized by the CDC, are *B. anthracis* (anthrax), *Y. pestis* (plague), variola major (smallpox), *C. botulinum* toxin (botulism), *Francisella tularensis* (tularemia), filoviruses (Ebola hemorrhagic fever, Marburg hemorrhagic fever), and arenaviruses (Lassa [Lassa fever], Junin [Argentine hemorrhagic fever], and related viruses).²⁷

Epidemiology in bioterrorist incidents is not too different from standard epidemiological investigations.³⁹ First, laboratory and clinical findings are used to confirm that an outbreak has occurred, using case definitions to determine the number of cases and attack rate. To characterize unusual levels of activity, the attack rate for the disease in question is compared against that of previous years to measure deviation from the norm. The outbreak can then be characterized in terms of time, place, and person, lending crucial data to determine the origin of the disease.³⁹ By analyzing data of cases over time, an epidemic curve can be calculated that will allow for differentiation between an outbreak and normal pattern of disease.³⁹ However, if an intentional release of a biological agent is suspected, time is of the essence, and as previously emphasized, early detection is key. Therefore, the development of surveillance systems, including syndromic surveillance systems and real-time computer models, are being developed. Surveillance “concentrates on the incidence, prevalence, and severity of illness or injury due to ecological changes, changes in endemic levels of

disease, population displacement, loss of usual source of health care, overcrowding, breakdowns in sanitation, disruption of public utilities, monitors increases in communicable diseases, including vector-borne, water-borne, and person-to-person transmission” and ultimately helps one to determine an association between exposure and outcome, whether that outcome includes specific injuries, illnesses, or death.²⁰ In setting up a surveillance system, managers should consider using existing systems, such as those used to track reportable diseases, or developing temporary systems to track specific injuries and illnesses before, during, or after the disaster.²⁰ Primary and secondary sources of data need to be identified and can vary from patient medical records (primary) to victim surveys and interviews (secondary). Primary data collection methods are direct observations or surveys, and secondary methods are interviews with key informants or review of existing records.²⁰

Data sets can be obtained from numerous places, including state hospitalization data, hospitals and clinics, private providers, insurance companies, temporary shelters, first responders, and mobile health clinics.²⁰ Increasingly, nontraditional data sources such as worker sick days from employer records are being used to screen for disease outbreaks. Next, case definitions need to be developed for uniformity of reporting outcomes. Finally, appropriate analytical methods should be used and can include descriptive measures, geographical analysis of spread, rates of disease or death, or an analysis over time measuring total numbers of cases and rates of appearance.²⁰ It is also important to remember that in a disaster situation, rigorous epidemiological approaches may not be time-conducive and that there will be an immediate need to quickly collect key, important data that may be perishable as time goes on and populations change in exposure and impact to the hazard. As a result, disaster situations invoke the use of “quick and dirty” data collection, “quick” being simple and flexible and “dirty” being that some quantitative data are rough estimates gathered to answer immediate questions.¹⁸

Increasingly, for bioterrorism purposes, health departments are developing and testing syndromic surveillance systems. *Syndromic surveillance* is “an investigational approach where health department staff, assisted by automated data acquisition and generation of statistical alarms, monitor disease indicators continually (real-time) or at least daily (near real-time) to detect outbreaks of diseases earlier and more completely than would otherwise be possible with traditional public health methods (e.g., by reportable disease surveillance or telephone consultation).” Syndromic surveillance uses nontraditional data sources, or those other than laboratory data. These data reflect events “that precede clinical diagnosis, such as emergency department chief complaints, clinical impressions on ambulance run sheets, prescriptions filled, retail drug and product purchases, school or work absenteeism, and constellations of medical signs and symptoms in persons seen in various clinical settings.”⁴⁰

CDC deployed field teams to New York City emergency departments on Sept. 14, 2001, to conduct surveillance for possible covert biological releases. For the first two weeks, epidemic intelligence service officers (EISOs) staffed 15 hospitals for 24 hours and then provided 18-hour coverage at 12 hospitals for the remaining 30-day surveillance period. The teams entered data on-site and reported data to the New York City departments of Health and Mental Health each morning and followed up on significant cases. Between Sept. 13 and Oct. 12, 68,546 emergency department visits were recorded, with trauma as the highest syndrome-to-none-ratio (SNR) found (18.6%), followed by exacerbation of a chronic respiratory condition (7.6%). Diarrhea/gastroenteritis (4.4%) and upper and lower respiratory infections (4.2%) were also reported. Children younger than 15 years presented most often with respiratory syndrome complaints (67%) and rash syndromes (59%). Those between 25 and 64 years old made up 80% of inhalational visits and 75% of anxiety visits. Analyses were also specifically conducted for home postal codes within a two-mile radius of the World Trade Center and revealed that persons in the two-mile radius were no more likely to have a syndrome of bioterrorism interest than those who were outside of that proximity. However, the study found that people in close proximity to the towers on Sept. 11 were 61.5 times more likely to visit the emergency department for smoke/dust inhalation complaints than people from other areas. Overall, no health data to support a bioterrorist release were found.⁴¹

CONCLUSION

Historically, promoting and managing the health of a society have shown to increase the welfare of the community. This discipline, called public health, is a broad one, encompassing multiple sectors of the community and professional fields; government and nongovernment agencies; and local, regional, federal, and sometimes international institutions. Collectively, these groups respond to disasters to study, reduce, and develop ways to mitigate adverse health effects in the future. This chapter has summarized phases of the disaster cycle, the players involved, and the basic policy of disaster declaration and response. Additionally, we have reviewed components of public health infrastructure, provision of medical services, education and communications in disasters, mental health issues, worker safety, and finally the value and techniques of data collection and analysis.

It is recommended that the newcomer to public health and disaster medicine review the many references in this chapter and refer to resources on the Internet. Importantly, responders should be proactive and become trained, well-informed, experienced providers and openly disseminate factual knowledge to the community and their peers. This is the beginning to a more efficient, life-saving public health response to disasters.

The Role of Emergency Medical Services (EMS) in Disaster

Robert D. Furberg and David E. Marcozzi

The role of emergency medical services (EMS) systems in disaster management is to provide effective, responsible prehospital care; however, multiple considerations must be made long before the first EMS unit arrives on scene. Disaster management may be examined in the following four phases¹:

1. Prevention and planning
2. Preparedness
3. Response
4. Recovery/analysis

The process of prevention and planning uses an effective application of the hazard vulnerability analysis (HVA) concepts discussed briefly later in this chapter and in more detail in Chapter 17. The HVA establishes the probability of risk and identifies key components of an operative response plan. Measures to reduce potential loss of life and property may be achieved through the combined effort among members of the jurisdiction's local emergency planning committee (LEPC) and other participants in incident response.

Preparatory functions of management personnel must occur to ensure that responders, emergency managers, and citizens are adequately informed of and trained on appropriate operational expectations.

During the response phase, public safety personnel must implement the Incident Command System early and effectively. Once operating within the paradigm, responders assume the specific tasks required to mitigate the incident. Triage, treatment, and transport are the highest priorities for most paramedics and emergency medical personnel. Specialized medical units with the necessary training and equipment may assume additional duties as directed by the incident commander.

Initial and long-term recovery efforts are directed toward the reconstruction and rehabilitation of infrastructure and the community. EMS systems usually do not serve a primary role in recovery, but this final phase of management is critical for system reassessment and improvement. Analysis of specific methodologies used during incident management, including the efficacy of triage and predictive outcome assessments, are useful to the global community.²

After their inception on the battlefield, modern civilian EMS systems have found themselves using many of the same techniques, under similar conditions, as the pioneers of the field when managing disasters domestically. Modern EMS systems are capable of moderating the daily burden of emergencies; however, disaster operations often require emergency services to assume a different perspective to ensure effective resolution of significant incidents. This chapter details the operational adjustments that have been designed to optimize the role of EMS in disaster management.³

HISTORICAL PERSPECTIVE

EMS is a product of war. From the first organized use of ambulances on the battlefields of Crimea to the birth of the modern field medic in the jungles of Vietnam, the history of EMS is undeniably blood-tinged with rich militaristic tradition.

Baron Dominique-Jean Larrey, Napoleon's surgeon-in-chief, is largely credited with placing the first ambulance in service more than 150 years ago during the Crimean War. Larry, well-versed in the critical nature of traumatic injuries, initiated the use of covered, horse-drawn carts to expedite the movement of injured soldiers to treatment areas. This improvement drastically reduced the number of ineffective combat troops recovered from battle.

During the Civil War, Clara Barton coordinated and rendered emergency care to wounded infantry. After serving as the superintendent of Union nurses, she crusaded tirelessly for medical relief of sick and wounded soldiers. Barton established the Red Cross within the United States, serving as the organization's first president. During her tenure, she directed relief work for disasters such as famines, floods, pestilence, and earthquakes in the United States and throughout the world.

With the improvement of military technology, casualties increased. As a consequence, soldiers received greater training in the management and transport of injured infantry during World War I. Aeromedical transport systems were established during World War II and refined during the Korean conflict.⁴

The corpsman of Vietnam most closely resembles the paramedic of today. Personnel were well trained in a variety of increasingly advanced interventions. Care was often rendered in extreme environments to multiple patients at once. The military demonstrated a profound effect on battlefield mortality rates with the aggressive application of early advanced intervention and expeditious transport via helicopter from the front lines of engagement to definitive care installations. The evolution of trauma care in military medicine proved to be the major factor in a progressive decrease in casualties among compromised soldiers. Casualty rates were reduced from 8% in World War I to 4.5% in WWII to 2.5% in the Korean War to less than 2% during the Vietnam conflict.⁵ Despite aggressive engineering feats that mechanized warfare and drastically increased the power of ordnance, the medical experience gained from the two World Wars and multiple international conflicts resulted in fewer soldiers killed in combat. The shift from empiricism to the practice of evidence-based medicine and the provision of acute care in the field made armed conflict much more survivable. The immense benefits of rapid, advanced field stabilization and swift transport to definitive care facilities realized by the armed services would soon become the expectation of politicians and civilians alike in the United States.

After the advances made in trauma care on the battlefield, researchers in the United States during the early 1960s found that an infantry soldier in Vietnam had a statistically greater chance of survival than the average citizen involved in a motor vehicle collision on any of the nation's highways. This disparity prompted two significant legislative acts in 1966. First, the National Academy of Sciences-National Research Council (NAS-NRC) published *Accidental Death and Disability: The Neglected Disease of Modern Society*. This white paper put forth 11 recommendations to improve care for injured persons. Recommendations included the creation of various standards within EMS, including training, public safety infrastructure, and the creation of "... a single nationwide number to summon an ambulance." The second bill prepared by Congress was the Highway Safety Act of 1966. This act mandated the creation of the U.S. Department of Transportation (USDOT) and the National Highway Traffic Safety Administration (NHTSA). Both entities provided legislative authority and financial assistance to EMS systems in the United States. Between 1968 and 1972, approximately \$142 million was distributed among states to develop and assess the first advanced life support programs.

Initial training centered on the kinematics of trauma, stabilization, and provision of appropriate transport to definitive care facilities. Over the last three decades, EMS systems in the United States have established their own niche within the public safety sector. Paramedics have become increasingly autonomous as a result of the steadily expanding complexity of medical conditions and treatment options. In addition to these advancements, EMS systems have remained a reliable resource on the "domestic battleground," where individuals in need of assistance may exceed available resources. To ensure that an EMS system is used most effectively in large-scale incidents, a specific, highly organized structure was developed.

However, before that structure was established, major incidents in the civilian sector routinely required the response of several agencies. Effective management was often confounded by multiple entities performing independently of one another without adequate interaction or communication. A significant example of how impaired communications can poorly affect the outcome of event mitigation can be demonstrated by what occurred after the attack on the World Trade Center on Sept. 11, 2001. New York City's Office of Emergency Management (OEM) assumed its current form in 1996 and was headquartered at 7 World Trade Center.^{6,7} Communications from OEM were based off an antenna atop 1 World Trade Center. Less than nine hours after the first strike, 7 World Trade Center collapsed, significantly impairing coordinative abilities among EMS, the New York Police Department, and the Fire Department of New York. Responders lacked the common resource to communicate reliably among these agencies due to the lack of radio frequency interoperability. Additionally, triage and transport of patients were adversely affected by the lack of coordinated communications with local and regional hospitals in the New York City metropolitan area.^{8,9}

During the early 1970s, fire administrators in California developed the Incident Command System (ICS) to manage rapidly moving wildfires and operational deficits that were previously encountered. Specific complications cited before the creation of the ICS included "too many people reporting to one supervisor; different emergency response organizational structures; lack of reliable incident information; inadequate and incompatible communications; lack of structure for coordinated planning among agencies; unclear lines of authority; terminology differences among agencies; and unclear or unspecified incident objectives." In 1980, federal officials developed a national program called the National Interagency Incident Management System (NIIMS) based on the original ICS construct. The inherent flexibility of the ICS to accommodate issues of incident size and utilization of available resources has allowed the system to be used to mitigate both minor crises and major disasters exacted by nature and humans alike. As public safety personnel developed familiarity with the ICS, the federal government identified the need for the development of a body of government to establish standards of practice within increasingly complex applications of disaster management. In response to the increasing threat of terror attacks and the need to ensure a more cohesive response to large-scale incidents, federal guidelines were created to establish the role of EMS.^{10,11}

In 1998, Congress issued a report underscoring concern regarding "... the real and potentially catastrophic effects of a chemical or biological act of terrorism." Legislators indicated that although the federal government is integral in the prevention and secondary response to such incidents, state and local public safety personnel who respond initially require additional assistance. The Appropriations Act (Public Law 105-119) authorized the U.S. attorney general to aid state and local responders in acquiring specialized training and equipment to "... safely respond to and manage terrorist incidents involving weapons of mass destruction (WMD)."

The U.S. attorney general delegated authority to the Office of Justice Programs (OJP) on April 30, 1998, to develop and administer training and equipment assistance programs for state and local emergency response agencies. To accomplish this mission, the Office for Domestic Preparedness (ODP) was established to develop and administer a national domestic preparedness program.

On Oct. 8, 2001, by executive order, the Office of Homeland Security and the Homeland Security Council were established. The functions of the newly created offices included incident management and oversight of preparation, response, and recovery after terrorist incidents. The Homeland Security Act of 2002 formally established the Department of Homeland Security (DHS). In the most significant federal restructuring since the 1960s, the newly anointed DHS has been placed in command of 22 government agencies, including the Federal Emergency Management Agency.¹²

CURRENT PRACTICE

The role of EMS in the disaster management paradigm incorporates the four-phase approach of prevention and planning, preparedness, response, and recovery/analysis. These key phases have defined the mitigation of crises of all sizes since their inception in the early 1970s. After the establishment of the DHS and ODP, both agencies issued guidelines for municipal, state, and federal responders within public safety. These guidelines, in conjunction with the serial reassessment of current practice methodologies, allow responders to ensure that the most appropriate management strategies have been selected for a given situation. Adhering to the use of this construct allows EMS systems to optimize their ability to react to disaster.^{13,14}

The prevention and planning phase includes the identification of specific hazards, threat assessments to life and property, and preemptive steps to minimize potential losses. Measures to reduce potential loss of life and property are commonly referred to as *disaster mitigation*. Mitigation measures may include public awareness campaigns, LEPC involvement, and legislative action.

Preparedness encompasses the training and education of both public safety personnel and members of the community. The DHS has specified the ODP as the lead agency for directing domestic preparedness efforts and creating standards for the implementation of response plans. Under executive order, the National Disaster Medical System (NDMS) was formed in 1983. With cooperation between local communities and the federal government, Disaster Medical Assistance Team (DMAT) and International Medical and Surgical Response Team (IMSuRT) resources have developed throughout the nation. These deployable teams are designed to be a rapid-response element to supplement local medical care until contract resources or federal assistance can be mobilized. The responsibility of DMATs may include triaging patients, providing high-quality medical care despite the challenging environment found within disaster scenes, and assisting with patient evacuation. EMS

personnel who participate in operations involving a DMAT deployment often are used in more of a primary care role rather than their typical emergency response capacity. The development of a strong relationship among primary care facilities, providers, and EMS systems regionally during the planning phase of action may significantly improve the transition of EMS personnel into this role. The NDMS also ensures that teams are equipped to sustain operations for 72 hours without additional resources. This dramatic difference underscores the disparity between routine and extended operations. Typically, EMS systems and personnel may be equipped or prepared to function for 24 to 48 hours; however, major disaster scenes are rarely mitigated completely without a more significant time commitment.¹⁵⁻¹⁷

On Aug. 1, 2002, the ODP released its *Emergency Responder Guidelines* to assist agencies in establishing a baseline understanding of the training necessary to safely and effectively respond to incidents involving the use of WMD. Designed and compiled as a resource, the guidelines present advice of experts from the private and public sectors. The guidelines were prepared with assistance from key federal agencies involved with first-responder training and incorporated existing codes and standards established by the National Fire Protection Agency and the U.S. Occupational Safety and Health Administration. The guidelines provide an integrated compilation of baseline knowledge, skills, and responder capabilities for use as a reference by providers as well as course developers and trainers to underscore the importance of interoperable response strategies. The *Emergency Responder Guidelines* specify training objectives and establish the baseline level of operational knowledge of three distinct levels of responsibility—awareness, performance, and management—required of specific response disciplines (Table 3-1). Training is based on a provider's level of experience and operational accountability with the three levels of responsibility. Commonalities among specific response disciplines (e.g., law enforcement, fire, EMS) illustrate areas in which common training and understanding can be established to ensure a more cohesive operational response.^{18,19}

Awareness-level guidelines pertain to law enforcement officers, firefighters, and basic level emergency medical technicians. At a minimum, response personnel within this category are expected to be among the first to encounter an incident. Once management operations are under way, awareness-level personnel assume a more supportive role. These providers are responsible for recognition and referral after encountering a hazardous environment. The training objectives establish a basic understanding of operational actions, including notification of need for additional specialized resources, maintenance of scene control, and demonstrated competence of self-protection measures.

Performance-level guidelines apply primarily to advanced level providers on scene, including paramedics and firefighters involved in rescue or fire suppression operations or a hazardous materials event. Depending on the various ICS assignments in use during a given incident, the performance-level providers must efficiently multitask their primary responsibilities with additional

TABLE 3-1 LEVELS OF RESPONSIBILITY

AWARENESS	PERFORMANCE	MANAGEMENT
Recognize hazardous materials (HazMat) incidents.	Have successfully completed proper training at awareness and performance levels.	Have successfully completed proper training in awareness, performance, and management levels.
Know protocols used to detect WMD agents or materials.	Know ICS and UCS, and assist with implementation as needed.	Know and follow ICS and UCS procedures. Understand how the systems are implemented and integrated.
Know and follow self-protection measures for WMD and HazMat events.	Know and follow self-protection measures and rescue and evacuation procedures.	Know and follow protocols to provide emergency medical treatment to persons involved in the event.
Know procedures for protecting a potential crime scene.	Know and follow procedures for working at the scene of a potential WMD event.	Know and follow self-protection measures.
Know and follow agency's or organization's scene security and control procedures for WMD and HAZMAT events.		Know plans and assets available for transporting the victims of events to primary care facilities.
Possess and know how to properly use equipment to contact higher authorities to request additional assistance or emergency response personnel.		Know and follow procedures for protecting a potential crime scene.
		Know and follow department procedures for medical monitoring of response personnel involved.

Adapted from Office for Domestic Preparedness. *Emergency Response Guidelines*. August 1, 2003.

assignments from their commander. As a consequence, performance-level personnel require a strong working knowledge of the ICS and the ability to follow the Unified Command System (UCS). The provider must be able to follow procedures for the integration and implementation of each system and know how the two structures can be used to manage the incident. Procedures include establishing adequate communication capabilities to manage the incident; securing triage, treatment, and transport areas; and coordinating multiple responding agencies. The performance-level responder must also demonstrate competence in self-protection measures, rescue and decontamination operations, and evacuation procedures for managing victims.

Planning-level and management-level providers are typically service administrators, supervisors, and emergency management officials. Those who operate within these guidelines must first complete both awareness-level and performance-level objectives. Individuals responsible for training at this level will be a part of the leadership and management of subordinate emergency medical personnel during the response operation. Objectives include planning before the incident as well as managing resources used to conduct the event. Leadership personnel must also be capable of overseeing medical surveillance of subordinates.

In accordance with the preparatory phase, the ODP offers multiple training opportunities for responders at all levels. To enhance the capacity of local and state agencies, the ODP's Equipment Grant Program provides funds to 50 states, the District of Columbia, the Commonwealth of Puerto Rico, American Samoa, the Commonwealth of Northern Mariana Islands (CNMI), Guam, and the U.S. Virgin Islands.²⁰

The priority among EMS responders must be rendering responsible prehospital care. To enable this goal, responders must first integrate an ICS into their response plan to allow for effective management of an incident.

During the response phase, multiple responders and agencies must be coordinated to operate effectively. Civilian responses routinely incorporate the responsibility of several different specialties, such as fire and rescue, EMS, and law enforcement, beneath a single commander. As the scale of an incident grows, the command structure must expand to meet the increasingly diverse needs to provide effective management. With large-scale incidents, the underlying organizational construct becomes even more critical as coordination extends to incorporate local, state, and federal resource allocation.

All responders on scene must be familiar with the structure and function of the ICS and UCS. The ICS enables integrated communication by establishing a manageable span of control. Beneath a single incident commander (IC), subordinate commanders exercise their own span of control among context-specific divisions. The overall structure of the system describes four divisions beneath the IC, including operations, planning, logistics, and finance. With each application of the ICS, commanders may elect how to delegate these various designations among responders. The benefits of operating within the ICS structure are apparent. First, the role of every responder on scene is clearly defined by the commander. Leadership responsibilities are delegated, optimizing the ability of each officer to complete very specific tasks. Ability to ensure the fulfillment of every critical intervention is simplified.

As local responders arrive, an initial ICS system is established to manage resources. Upon the arrival of additional local, state, federal, and private-party personnel, the ICS structure may be modified to accommodate the expanding operation. The purpose and function of the UCS is to allow for expansion of the initial ICS structure. When operating within a large-scale incident, the UCS allows for the unification of multiple ICs. The IC is responsible for overall management of the incident and directs incident activities, including development and implementation of overall objectives and strategies as well as the ordering and releasing of resources. Members of the UCS work together to develop a common set of incident objectives, produce strategies, share information, maximize the use of available resources, and enhance the efficiency of the individual response organizations.

The final phase of disaster management is the process of recovery/analysis. Initial recovery is the method by which an affected community is assisted in regaining a proper level of functioning after an incident. Long-term recovery addresses community-specific deficits of reconstruction and rehabilitation. The roles of EMS systems in these direct recovery processes are usually limited; however, systems must address their own logistical and psychological recovery so that they can return to a proper level of functioning after an incident. Specifically, equipment must be accounted for and repaired if necessary and disposable supplies must be replaced and organized. A critical function of recovery within an EMS system must also account for responder well-being. Critical incident stress debriefing (CISD) or jurisdictional peer-moderated counseling may accommodate the personal recovery necessary to resume normal operations. Alternatively, this phase affords the EMS system the opportunity to engage in critical analysis of its own performance during the incident. The opportunity to engage in self-assessment is critical in identifying system weaknesses that may be targeted in future improvements as well as create the forum for commending personal actions that had a positive influence on the outcome of an incident. On completion, this analysis offers evidence that may be used to support the use of specific methodologies.²⁰⁻²³

Although also considered an element of preparation, exercise planning and evaluation programs provide valuable data for review. The ODP's Homeland Security Exercise and Evaluation Program provides state and national opportunities for evaluating response methodologies. For example, the ODP conducted the Top Officials (TOPOFF 2) exercise May 12-16, 2003. The event was the largest of its kind, involving 25 federal, state, and local agencies and departments and the Canadian government to test domestic incident management. The exercise simulated the detonation of a radiological dispersal device in Seattle, Wash., and the release of the pneumonic plague in several Chicago metropolitan areas. There was also significant pre-exercise intelligence play, a simulated cyber-attack, and credible mock terrorism threats against other locations. After the completion of the exercise, significant discussion was initiated to critique the response. After extensive review, DHS provided a detailed after-incident report for public release on Dec. 19, 2003.

The "T2 After Action Summary Report" cited multiple topics of interest following analysis. Critical shortcomings were noted within the Homeland Security Advisory System. Participating jurisdictions failed to agree on reaction to the elevation of the nation's threat condition to "red/severe" for the first time; declarations of "disaster" and "emergency" by officials revealed confusion among interagency responders. During the exercise, DHS used the newly developed role of principal federal official (PFO) in an effort to create a single position of accountability to bridge federal and local governments. Evaluators observed integration of the PFO within ICS/UCS paradigms. In addition, logistically complex prophylaxis distribution from the Strategic National Stockpile was evaluated. Challenges associated with resource allocation, communications, and information-sharing during the mock public health emergency illustrated the need for improvements within the participating municipal systems. Operationally, balancing the safety of first responders and the rescue of victims by conducting a detailed risk-benefit analysis was deficient among participants functioning at the planning/management level.

Analysis of significant incidents worldwide may also offer some compelling data. Modeling triage methods based on the predictive value of anatomical scoring systems has revealed evidence-based, outcome-driven improvements in field triage and resource allocation. Significant analysis of the outcome among blunt and penetrating trauma patients provided the framework for the Sacco Triage Method. Support for improvements in the management of disaster result only from effective analysis. Due to the globalization of healthcare and mitigation, the resulting data from events worldwide must be delivered in a useful format. Application of the Utstein template may be useful to ensure international value of data by standardizing terminology and significance. Originally created to classify data used to determine cardiac arrest survival rates and allow for international comparison of statistically similar events, the Utstein method has been applied to disaster outcome in recent years. Applying sound epidemiological methods to postincident management is critical to the reduction of empiricism within disaster medicine methodology.²⁴

PITFALLS

The role of EMS systems in a disaster is to provide responsible prehospital care to victims. To facilitate this objective effectively, EMS personnel must use the ICS/UCS and effective triage methodology. Multiple, universal shortcomings must be addressed even before responders find themselves on the scene of a major incident. Systems easily succumb to inadequacies in the prevention/preparation phase despite the widespread availability of federal training resources and funding. Specifically, failure to provide appropriate HVA, inexperience among responders in the application of ICS, and shortsighted planning on the part of management-level personnel allow for massive deficits in domestic response.

HVA describes the process by which potential events are scrutinized using three categories: probability, risk,

and preparedness. Probability is determined by analyzing the known direct risk, relevant historical data, and any additional pertinent statistics. The risk assessment defines potential totals among lives, property, financial, and legal stature. Finally, preparedness integrates the overall value of probability and risk into a cohesive plan that dictates training requirements, contingency plans, and resource allocation. On completion, the HVA allows managers to consider common elements within preparedness procedures. These priorities are then used to direct a coordinated and integrated effort among all necessary participants within incident management, affording an ease of transition into the ICS/USC paradigm. Widespread failure to adequately address HVA has direct implications on the effective establishment of ICS/USC during the initial response phase of an incident.

Improper or inadequate training in the use of the approved ICS structure may further complicate an incident during the initial response phase. Failure to acknowledge the importance of a properly functioning leadership model can quickly overwhelm the entire operation. It is critical for responders to understand that implementation of a dynamic command structure, which can expand as needed and easily integrate multiple responding agencies, may precede actual patient care. As a part of the initial assessment by the IC, a detailed risk-benefit analysis must be confirmed to ensure environmental suitability for rescue efforts to even begin. Providers are easily overwhelmed when inadequate resources impair their ability to provide emergency care to those in need. The greater critical failure in this example becomes clear as direct threats to rescuers greatly impede the success of an entire incident. Fortunately, all EMS personnel are taught the basic concepts of ICS in every initial certification course in the United States. It is imperative that agencies recognize the importance of establishing an ICS, whenever reasonable, to maximize exposure and operational familiarity among all responders. As a matter of practical familiarity, services should mandate the use of an ICS at every opportunity. The benefit to personnel at the awareness and performance levels becomes clear. As these providers gain real-time experience with the implementation of the ICS structure, delegation among divisions, and transition of command, they become more reliable with the application of the ICS concept. With repeated use, the responders use the techniques with more certainty, regardless of incident size.

Planning and preparation phase failure is extremely common and evident more so in stationary healthcare facilities. Although EMS systems have used proactive measures to ensure preparedness, many are wholly unprepared for significant events within their jurisdiction. Probability is a significant factor within the HVA process previously detailed. Minimal preparation in light of minimal risk is appropriate; however, systems must ensure that all potential incidents are adequately addressed. Despite a decreased risk within a single response area, managers must consider all aspects of mutual aid agreements, neighboring HVA results, preparation phase actions, and cohesive integration of multiple adjacent agencies. Recognizing the

failure to address critical aspects of local and regional planning/preparation efforts and effective program integration, while costly, is better managed during a jurisdiction's preincident phase rather than after the event.

Role of Emergency Medicine in Disaster Management

Andrew I. Bern

To understand the role of emergency medicine in disaster management, one needs to understand the development and evolution of the specialty of emergency medicine, disaster medicine and disaster medical services, emergency medical services (EMS), emergency management, public health, and legislative interventions by government and nongovernment entities during the last 50 years (Table 4-1). This chapter highlights historical events that helped mold the current practice of disaster management and shines light on areas that need improvement.

Although disasters have global importance, there are differences in the approach to disaster management in the United States when compared with the rest of the world. This may, in part, be due to the nature of historical disasters in the United States. In the area of lives lost in the United States before 1987, for example, Quarantelli¹ identified only six disasters with deaths exceeding 1000 individuals. These disasters occurred between 1865 and 1928 and included two hurricanes, two fires (one on board a steamship), a flood, and an explosion on board a steamship.¹ The loss of life in the United States is contrasted by disaster events that have occurred in the rest of the world. The 1917 influenza pandemic resulted in 20 million deaths worldwide. The Soviet Union famine in 1932 left 5 million dead. A 1931 flood in the Republic of China resulted in the death of 3.7 million. A Nov. 13, 1985, volcanic eruption in Colombia resulted in the death of 21,800.² Flash floods killed approximately 2000 people in Mapou, Haiti.³ More recently, more than 200,000 were killed in the tsunami of southeast Asia in December 2004.

Death tolls alone do not tell the whole story. Hurricane Andrew, which battered the United States from Aug. 14 to 27, 1992, was the costliest natural disaster in U.S. history. Total costs for both Florida and Louisiana equaled \$26 billion. The cost was also felt in the homes and businesses destroyed and the population left homeless in south Florida (between “150,000 to 250,000 people were left homeless with approximately 600,000 homes and businesses destroyed or severely impaired” by the effects of Andrew).⁴ Hurricane Andrew was a category four storm on the Saffir-Simpson Hurricane Scale, with sustained winds of 145 mph and gusts of up to 175 mph.⁴ These numbers may be dwarfed by the

total cost from damage caused by Hurricane Katrina striking the Gulf Coast of the United States in 2005.

Frequently, in nondeveloped or developing countries or those in the midst of conflicts and wars, the civilian population faces complex humanitarian emergencies. These events are multifaceted, of long duration, often involve large geographical areas, and are associated with famine and difficulty in providing or finding shelter. Many of these complex humanitarian emergencies include public health emergencies, with infectious disease outbreaks and loss of infrastructure. They often involve social, psychological, and political problems that have required the assistance of the world community—most often the United Nations, the International Committee of the Red Cross, and the interventions of multiple countries and other nongovernment groups.⁵⁻¹¹

Although there is a significant amount of social science and engineering research reported by the Disaster Research Center (Newark, Del.) and the Natural Hazards Center (Boulder, Colo.), there are few centers in pursuit of clinical, bench, or even “evidence based” research that supports how disaster medicine and emergency management are practiced.

HISTORICAL PERSPECTIVE

Those who cannot remember the past are condemned to repeat it.

George Santayana

The history of mankind’s fears and struggles with disasters and their aftermaths are as old as recorded history and man’s fear of death. In ancient times, pagan belief was that sacrifice, including human sacrifice, would appease their deities and avert their disasters, such as an erupting volcano, climatic catastrophes, and war. Recurrent fires and floods gave rise to systematic attempts to cope with these events. After a fire destroyed almost one quarter of Rome in 6 AD, Roman Emperor Augustus created the Corps of Vigiles. This was the first recorded professionally trained and equipped fire service.¹² Early fire mitigation and recovery programs, as

TABLE 4-1 TIMELINE OF DEVELOPMENTAL/SENTINEL EVENTS

YEAR	EVENT
6 AD	The Corps of Vigiles—first professional fire service established
13th century	England: Fire protection insurance becomes available
1666	Great Fire of 1666 in London—changes that took place after this disaster resulted in the model of today’s fire service
1798	Marine Hospital Service created (later to become the Public Health Service)
1917	Influenza pandemic
1931	Flood in China
1932	Famine in Soviet Union
1953	U.S. Department of Health, Education, and Welfare (cabinet level)
1954	Volcanic eruption in Colombia
1966	<i>Accidental Death and Disability</i> report by the National Academy of Sciences/National Research Council
1968	Foundation of American College of Emergency Physicians (ACEP) established
1973	Emergency medical services created
1979	Federal Emergency Management Agency formed FIREScope and Incident Command started Public Health Service is moved to Department of Health and Human Services
1983	Critical incident stress debriefing begins
1988	ACEP forms Section of Disaster Medicine
1991	National Fire Protection Association begins standard development
1992	Hurricane Andrew
1993	World Trade Center attack
1995	Oklahoma City bombing
1999	Federal Response Plan

2003	Homeland Security Presidential Directive/HSPD-5 calls for a National Incident Management System (NIMS) and a National Response Plan (NRP) Department of Homeland Security established
2004 (November)	States must file to qualify for predisaster hazard mitigation funds—threat assessments completed

well as building regulations and fire protection insurance, began to appear in England in the 13th century.¹² Today’s fire service is modeled after changes that were implemented after the “Great Fire of 1666 in London, which left 200,000 homeless and burned out the heart of the city.”¹² As evidenced in the *Bible*, mitigation principles were practiced by Noah when he constructed the ark. The first recorded mitigation project to prevent flooding occurred when Amenemhet II (pharaoh, 12th dynasty) created an “irrigation canal and a dam with sluice gates.”¹²

The Exodus story, in the Old Testament, refers to the 10 plagues (disasters) brought down on Egypt to persuade the pharaoh to let the Israelites leave. As man’s weapons have evolved from stones, to knives, to spears, to the use of explosives, guns, chemical, biological, and nuclear agents, so has the ability to medically cope with these consequences and minimize the impact of these events. We can trace and credit the modern approaches of today’s triage to concepts first introduced during the Napoleonic wars by Baron Dominique-Jean Larrey in the 18th century. The triage concept was simple—sort the patients by the severity of their injury and treat and stabilize the most critically injured first. In following this practice, the greatest good could be delivered to the greatest number of casualties. Surgical techniques and rapid frontline interventions were used during the Civil War. The concept of rapid evacuation after initial treatment to an advanced treatment facility demon-

strated a significant reduction in mortality during the Korean and Vietnam wars when compared with World War II. In 1966, a report was released by the National Academy of Sciences/National Research Council, *Accidental Death and Disability: The Neglected Disease of Modern Society*. The report called for applying these military lessons learned to civilian society. Ultimately, it gave rise to what is currently thought of as EMS in 1973.

Emergency Medicine

In the early 1960s, a patient’s personal physician or a physician from the hospital medical staff, who was on rotation for the day, provided medical care for patients who showed up in the “emergency room.” The first full-time providers of care exclusively in the “emergency room” began appearing in 1965. In 1968, the American College of Emergency Physicians (ACEP) was established in Lansing, Mich. Its mission was to educate physicians in this new practice environment (i.e., emergency medicine) and to improve the quality of care to these patients. ACEP did this by developing and periodically revising a “core content of Emergency Medicine”¹³ and by creating the American Board of Emergency Medicine in 1976, resulting in approval from the American Board of Medical Specialties for a modified conjoint board in 1979 and primary specialty board in 1989 (with emergency medicine becoming the 23rd medical specialty). ACEP also developed training through residencies in emer-

gency medicine (with the first graduate in 1970), educational conferences, and a research agenda to further define and develop the specialty.

Disaster Medicine and Disaster Medical Services

By 1976, the ACEP published *The Role of Emergency Physicians in Mass Casualty/Disaster Management*.¹⁴ This policy was later approved (1985), reaffirmed (1997), and revised and expanded (2000).¹⁵ (See Box 4-1 for the full policy statement.) In this policy, “ACEP believes that emergency physicians should assume a primary role in the medical aspects of disaster planning, management, and patient care.” It also calls for emergency physicians to participate in “local, regional, and national disaster networks.” The University Association of Emergency Medicine echoed the calls for training in disaster medicine and further called for the development of fellowship training in disaster medicine.¹⁶ The ACEP also was an advocate for emergency physician participation in the “development of comprehensive plans developed by communities” to cope with disasters and of the National Disaster Medical System through disaster medical assistance team (DMAT) participation (1985, revised 1999).¹⁵ The ACEP Section of Disaster Medicine was formed in 1988. Through continued involvement and advocacy of disaster medicine, section members are participating on many levels: participation in DMATs, research and writing, educational conferences, and hospital and community disaster and emergency management.

Emergency Medical Services

Today, EMS and disaster medical services are linked through the first responder (emergency medical technician EMT, paramedic, firefighter, law enforcement representative, nurse, and emergency physician).¹⁷ Whether it is a fire, transportation, or hazardous materials incident, it is the first responders from the local EMS unit who determine whether adequate resources are available to address the incident. These first responders also are in a position to determine whether there are any injured people who need to be triaged, stabilized, and transported to a definitive medical facility. This unity of purpose was not always so. Disaster management developed from a civil defense model after World War II, with a focus on mitigation and preparedness. EMS developed from an applied military model, with a focus on response. EMS (as an outgrowth of its relationship with fire services) was the first to adopt the Incident Command System.¹⁸

Emergency Management

The Federal Emergency Management Agency (FEMA) can trace its beginnings to the Congressional Act of 1803. In this first federal disaster legislation, “assistance was provided to a New Hampshire town after an extensive fire.”¹⁹ Emergency management concepts developed from a civil defense model (“duck and cover”) to “protect” against a nuclear attack in the 1950s.

BOX 4-1 ACEP POLICY STATEMENT— DISASTER MEDICAL SERVICES

“The American College of Emergency Physicians (ACEP) believes that emergency physicians should assume a primary role in the medical aspects of disaster planning, management, and patient care. Because the provision of effective disaster medical services requires prior training or experience, emergency physicians should pursue training that will enable them to fulfill this responsibility.

A medical disaster occurs when the destructive effects of natural or man-made forces overwhelm the ability of a given area or community to meet the demand for health care.

Disaster planning, testing, and response are multidisciplinary activities that require cooperative interaction. Each agency or individual contributes unique capabilities, perspectives, and experiences. Within this context, emergency physicians share the responsibility for ensuring an effective and well-integrated disaster response.

Emergency medical services and disaster medical services share the goal of optimal acute health care; however, in achieving that goal, the two systems use different approaches. Emergency medical services routinely direct maximal resources to a small number of individuals, while disaster medical services are designed to direct limited resources to the greatest number of individuals. Disasters involving the intentional or accidental release of biological, chemical, radiological, or nuclear agents present an extremely difficult community planning and response challenge. In addition, they may produce a far greater number of secondary casualties and deaths than conventional disasters. Because the medical control of emergency medical services is within the domain of emergency medicine, it remains the responsibility of emergency physicians to provide both direct patient care and medical control of out-of-hospital emergency medical services during disasters.

Improvement of established disaster management methods requires the integration of data from research and experience. Emergency physicians must use their skills in organization, education, and research to incorporate these improvements as new concepts and technologies emerge.

Where local, regional, and national disaster networks exist, emergency physicians should participate in strengthening them. Where they are not yet functional, emergency physicians should assist in planning and implementing them.

This policy statement was prepared by the Emergency Medical Services Committee. It was approved by the ACEP Board of Directors June 2000. It replaces one with the same title originally approved by the ACEP Board of Directors June 1985 and reaffirmed by the ACEP Board of Directors March 1997.”

Reproduced with permission from American College of Emergency Physicians. Disaster medical services. *Ann Emerg Med*. August 2001;38:198-9.

Four significant hurricanes and two earthquakes in the 1960s and 1970s illustrated the need for national coordination and financial resources, which were beyond the capability of the local communities affected.

These disasters also moved the national mindset from civil defense to natural disasters. The National Emergency Management Association was established in 1974, consisting of state directors of emergency services and emergency management. In 1979, President Carter created FEMA by executive order (Executive Order 12148). To more effectively perform its function as an all-hazards emergency management program, multiple existing agencies were consolidated into FEMA. They included the Federal Insurance Administration, the National Fire Prevention and Control Administration, the National Weather Service Community Preparedness Program, the Federal Preparedness Agency of the General Services Administration, and the Federal Disaster Assistance Administration activities from Housing and Urban Development. In addition, civil defense responsibilities were transferred from the Department of Defense's Defense Civil Preparedness Agency.¹⁹

FEMA, like many in the field of emergency management, began to think in terms of the following four unique phases of a disaster incident:

- Mitigation
- Preparedness
- Response
- Recovery

Mitigation involves actions that could prevent a disaster or minimize its consequences. Lessons learned from the 1994 Northridge, Calif., earthquake affected building codes, engineering standards, and where structures were built.²⁰ In a similar way, mitigation actions for a hurricane would include preplanned evacuation routes, building codes, warning systems, and recommendations for family hurricane supplies. *Preparedness* and *planning* include taking steps to avoid or minimize the consequences of a threat through probability assessment, currently described as a "hazard vulnerability assessment (HVA)."²¹ An example would include a community or hospital disaster response plan based on threat assessments.^{26,27} *Response* includes all activities involved in bringing resources (supplies, personnel, and coordination) to an incident to minimize health consequences of the affected population and, where appropriate, providing security, rescue, triage, stabilization, and transportation to safety and definitive care. The involvement of government and private organizations to provide interventions is not only associated with response, but also with the fourth phase, recovery. *Recovery* includes actions needed to return the community to normal operations. Recovery may take weeks and months, or in the case of hurricane Andrew, more than a decade. In some cases, the community may never recover from a disaster incident.

In 1982, the International City Management Association conducted a national survey. Its finding was that "20% of local governments did not have a formal disaster plan."^{12,22} Almost a decade later, hospitals were not any better prepared. "According to the Joint Commission on Accreditation of Healthcare Organizations (JCAHO, 1990), only 21% of surveyed hospitals meet their requirements for disaster preparedness."²³ In 2002, the Homeland Security Act was passed, and in 2003 the Department of Homeland Security was created. FEMA

was transferred to the Department of Homeland Security, and the National Disaster Medical System was placed under FEMA's operational control.²⁴ Homeland Security Presidential Directive/HSPD-5 established a "single, comprehensive National Incident Management System."²⁵ The primary focus was to establish a national standard and improve interoperability between all involved agencies and organizations. This new standard replaces the National Fire Incident Command System.

CURRENT PRACTICE

Disaster management is a multidisciplinary practice that involves many professional disciplines. The complexities of this interdependent approach can be appreciated by reviewing the Federal Response Plan (1999). In this plan, Emergency Support Functions (ESFs) are categorized into the following 12 areas:

- Transportation
- Communications
- Public works and engineering
- Firefighting
- Information and planning
- Mass care
- Resource support
- Health and medical services
- Urban search and rescue
- Food
- Energy
- Emergency medicine (which functions within health and medical services in this plan)

The role of emergency medicine in disaster management can be viewed as one of three: a traditional role, an activist leadership role, or the role of a system integrator. Figure 4-1 identifies nine potential interactions within the system. At the core is the emergency physician-patient relationship (Fig. 4-1, 1). When a disaster strikes locally, every emergency physician will find the need to assume roles identified as 2 through 5 in Fig. 4-1, even if he has no experience in disaster medicine. The on-duty emergency physician will need to provide leadership to his department, hospital, EMS, and community. The emergency physician's duties will depend on specific "job actions" defined through the hospital's Incident Command System (a standard required by JCAHO)³⁰ and the disaster plan implemented by the hospital. One model is the Hospital Emergency Incident Command System.³¹ The roles identified as 1 through 5 in Fig. 4-1 are part of the local hospital response to any given all-hazards event. This is known as a level one local response. Level two and three responses (see Fig. 4-1) refer to the involvement of state and federal resources for incidents that are beyond the capability of the local or regional disaster response. The state and federal resources brought into play and the timeline involved define levels. A central theme in the mitigation, planning, response, and recovery preparations will be the self-reliance of the community for the initial 2 to 3 days, at minimum, after an event.

Current practice is also influenced by JCAHO standards that are used in hospital disaster management;

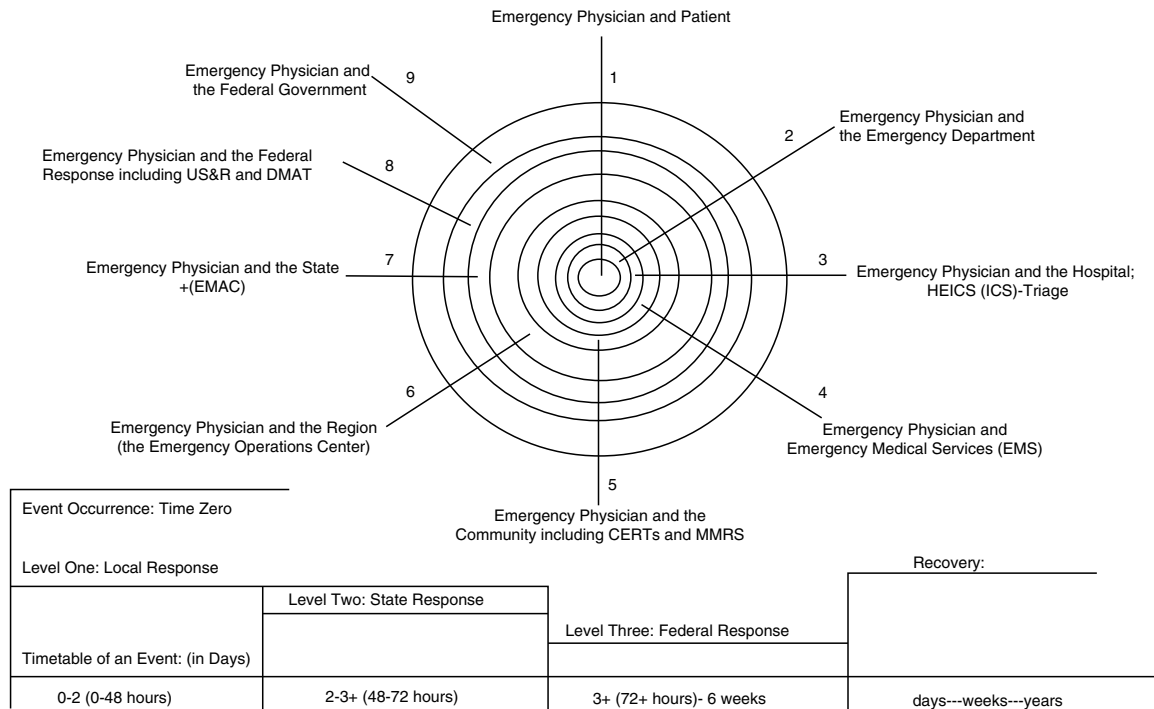

FIGURE 4-1. Rings of engagement: The different roles of the emergency physician in disaster medicine.

principles common to disaster incidents; and future directions, such as the movement to national standards and training.²⁸⁻³⁰

General Concepts and Definitions

Many of these are covered more extensively in other chapters of this textbook.

National Incident Management System

The National Incident Management System (NIMS) is a national best practice for incident management required by Homeland Security Presidential Directive/HSPD-5, "Management of Domestic Incidents."²⁵ The directive is to be implemented by fiscal year 2005 as a precondition for eligibility for federal preparedness assistance to state, local, tribal, or local organizations in their mitigation, preparedness, response, or recovery efforts. NIMS evolved from FIRESCOPE,¹⁸ the Incident Command System developed by fire services when battling the California wildfires in the late 1980s and which later grew into the National Fire Incident Command System.

National Fire Protection Association 1600

The National Fire Protection Association (NFPA) published *NFPA 1600: Standard on Disaster/ Emergency Management and Business Continuity Programs 2004 Edition*,³² a national best-practice, terminology, and reference resource developed through a consensus between public and private organizations. It is the culmination of work begun in 1991 by the Disaster Management Committee established by the NFPA

Standards Council. It was approved January 2004 as an American National Standard.

Convergence

Convergence is a behavior associated with the movement of people toward or away from a disaster event. It includes the unplanned arrival of individuals, including healthcare providers, who want to become involved in the rescue process. It also includes individuals from the impact zone of the disaster who find their own way, outside of the EMS system, to healthcare providers.

Mutual Aid

Mutual aid is used in the context of organized, preplanned coordination and use of resources from adjacent or remote organizations through the use of memoranda of understanding or contracts. An Emergency Management Assistance Compact (EMAC) is an example of shared resources between states.

Special Response Teams

Special response teams include community emergency response teams (CERTs), DMATs, urban search and rescue (US&R) teams, the Metropolitan Medical Response System, the National Response Team (NRT) for releases of oil and nonradiological hazardous substances, and other specialized teams. These resources are accessed through federal channels (taking up to 72 hours for implementation on-site), with the exception of the Metropolitan Medical Response System that is locally controlled and organized and the EMAC teams that are state controlled.

National Pharmaceutical Stockpile

The National Pharmaceutical Stockpile program is part of a level III federal response to provide pharmaceutical support to a medical disaster event.

Joint Commission on Accreditation of Healthcare Organizations

Eight months before the Sept. 11, 2001, World Trade Center disaster, JCAHO published a revision to its Environment of Care Standards (Box 4-2). One month after the disaster, on Oct. 10, 2001, JCAHO President Dennis O'Leary, MD, delivered testimony before Congress, stating: "Some people believe that the healthcare delivery system—if faced with a bioterrorism event—will somehow be able to accommodate the thousands of ill, injured, and worried well who will seek healthcare in that situation. The unfortunate truth is that we have much to do before such a belief can be fulfilled."

Current JCAHO standards encourage a comprehensive emergency management and "all-hazards" approach in which both internal and external threats are considered. The example of the Houston floods that caused the evacuation of Memorial Hermann Healthcare and Memorial Hermann Children's Hospital in the summer of 2001 lead to further changes in JCAHO standards that addressed emergency/disaster hospital privileging. The (ACEP) published a policy statement recommending the steps necessary to comply with these standards.³³

BOX 4-2 SUMMARY OF REVISED JCAHO STANDARDS

January 2001—Significant Changes

1. Shifting attitudes and practices from Emergency Preparedness to Emergency Management (mitigation, preparedness and planning, response, and recovery).
2. "All Hazards" assessment of threat using a Hazards Vulnerability Analysis (HVA) approach to include consideration of NBCEI (Nuclear, Biologic, Chemical, Explosive, and Incendiary) as well as natural and man-made events.
3. Healthcare organization Command and Control—an example, HEICS (Hospital Incident Command System). The purpose of which is to improve interoperability between organizations using a common system. This will include defining criteria for plan activation.
4. Community-wide practice drill with all departments within the hospital organization participating in a live simulation. The prime goal of the drill is evaluate all elements of the written plan and test the interoperability of the response structure, communication capabilities, coordination, and command and control.
5. Off site capacity/treatment is to be developed to include capability for decontamination and potential isolation and treatment of contagious patients and delivery of healthcare in home and at alternative sites.
6. Healthcare organization's integration with public health to include bi-directional surveillance communication, reporting, vaccination and treatment programs.

Principles Common to Disaster Incidents

It had been said that the best way to combat the fear of the unknown or unexpected is to understand it and anticipate it through study, characterization, and shining the light of preparation. We do not fear what we expect and understand. This is the driving force behind the various systems that are used to describe disaster events. Disaster category, class, and type demonstrate one means of classification. Time course of the event is another. A tornado strikes suddenly with little warning. A hurricane usually can be tracked with warning and preparation times of up to 72 hours. Following the rising tide, historical occurrences, monitoring riverbanks, or tracking precipitation can sometimes be used to predict floods. Multiple areas of destruction that take place over a large geographical area define some disasters. The Haddon matrix plots factors and elements such as the prodrome; impact; and recovery against human, structure, physical environment, and socioeconomic conditions in an attempt to better anticipate needs for preparation, response, recovery, and resource allocation.³⁴

Many of the principles associated with the four phases of disaster management—mitigation, preplanning and preparedness, response, and recovery—have been discussed (Table 4-2). Special treatment considerations and skills are associated with particular events. They include, but are not limited to, decontamination; treatment of blast injuries, crush and compartment syndrome, radiation exposure, shock, infectious disease, and injuries resulting from nuclear, biological, or chemical events; mass care; and humanitarian complex disasters. A seven-step process has been developed and is used in critical incident stress debriefing (a systematic program for psychological support developed by Dr. Mitchell in 1983 for first responders or affected members of the event).³⁵

Future Directions

The implementation of standard terminology and processes,³² education and training,³⁶⁻³⁹ coordination of the federal response through the Department of Homeland Security,²⁴ establishment of the National Response Plan,⁴⁰ adoption of the NIMS,²⁵ standardization of a pharmaceutical stockpile, standardization of training and equipment for specialty response teams such as DMATs, focused research through dedicated centers, and increased coordination and communication between interdisciplinary public and private organizations³² will lead to improved and enhanced capabilities in the area of emergency management.

PITFALLS

Today, our communities face increasing threats while after-action reports continue to recognize problems in 10 major areas (Box 4-3). These problems were evidenced in the results of the report from the National Commission on Terrorist Attacks upon the United States (also known as the 9-11 Commission), as documented by the *New York Times*. The lives of many of the first responders were lost due to problems identified in the report, including

TABLE 4-2 DISASTER PRINCIPLES ASSOCIATED WITH THE FOUR PHASES OF EMERGENCY MANAGEMENT

Mitigation	Threat assessments should include: <ul style="list-style-type: none"> ■ Hazard vulnerability assessment (HVA) ■ Historical events of high probability ■ Findings of agencies such as the National Oceanic and Atmospheric Administration
Preparedness	Take corrective and protective actions based on information learned during mitigation. Execute mutual-aid plans and memorandum of understanding.
Response	Out of hospital: <ul style="list-style-type: none"> ■ Impact-notification-verification-first responder actions, including establishing command and control—an Incident Command System (ICS). ■ Identification of hot, warm, and cold zones and a security perimeter. ■ Begin triage, stabilization, and documentation. ■ Transport to secondary assessment areas or definitive care within the healthcare organization with adequate communication. In hospital: <ul style="list-style-type: none"> ■ Implement the Hospital Emergency Incident Command System ■ Continue triage, stabilization, and treatment or discharge within the healthcare organization ■ Conduct appropriate documentation and communication with patients, family, media, and the community Other: <ul style="list-style-type: none"> ■ Activate and involve community organizations and public health.
Recovery	Interdisciplinary response that involves multiple organizations returning to normal operations Critical incident stress debriefing of first responders and community members

inadequate communication, inadequate coordination between police and fire rescue units with a history of jurisdictional battles (turf wars), and a lack of a functional, unified command.⁴¹ Air traffic controllers suffered “maddening miscommunications, mangled coordination, and broken chains of command. They (were) improvising a defense for a disaster for which they had never trained . . .”⁴²

Another problem area, as described Auf der Heide in 1989¹ based on the study by Quarantelli of 29 disasters in the 1970s, is maldistribution of patients among potential receiving hospitals. Auf der Heide reported that “in 75% of cases studied, a majority of the casualties were sent to the closest hospital. In 46% of the cases, more than three-fourths of the casualties were sent to the nearest hospital. Only in about half of the disasters did a simple majority of the hospitals in the area receive even one casualty.”¹ Casualty distribution during the Sept. 11 events underwent

these same problems. Most hospitals in a wide area had activated their disaster plans and were waiting for an influx of patients that never came. At the same time, the closest hospital to the World Trade Center site received more than 600 patients in the first day. The Greater New York Hospital Association, however, reported that “after the attacks, 7300 patients were seen at more than 100 hospitals scattered throughout the metropolitan region.”⁴³ This continues to point out both the lack of adequate plans for patient distribution on a regional basis and the challenge of appropriately capturing disaster epidemiology directly related to the disaster event as opposed to routine patient flow.

Preparation through the drilling requirements outlined by JCAHO is quite minimal when compared with the drilling practices elsewhere, such as Israel, where, as often as monthly, hospitals are tested without prior notification at up to 20% of their licensed bed capacity. In the United States, realistic drills and exercises have been cost-prohibitive as hospitals and communities have attempted to fulfill an underfunded mandate from organizations such as JCAHO.⁴³⁻⁴⁵

There are multiple triage systems currently in use without uniform standards or agreement as to a single tool that provides accurate triage and identification of critical injury for all patients in all situations.^{36,37,39}

Advancement of disaster medicine as a multidisciplinary professional specialty will require well-funded and organized research and the development of core content and competencies for its practitioners.⁴⁶ The United States after Sept. 11, 2001, has been in a crisis mode, catching up and plugging the holes.^{24,47} More than 20 pieces of significant legislation have been passed.⁴⁸ Recognition that national standards, training, exercising, and equipment have not been adequately funded in the past is supported by a report by the Council on Foreign Relations, chaired by Sen. Warren B. Rudman. The report, *Emergency Responders: Drastically Underfunded, Dangerously Unprepared*, details how bad the underfunding is. The monetary needs just for emergency responders in all jurisdictions (local, state, and federal) could equal \$201.4 billion over 5 years.⁴⁹

BOX 4-3 CHRONIC PROBLEMS: THE 10 C'S

1. Charge: who is in charge (operational control)?
 - a. Who has the authority to activate and deactivate the plan?
2. Command and control: the Incident Command System—lack of implementation (chain of command)
3. Communication
4. Coordination
5. Convergence (either the movement of unsolicited volunteers toward the disaster scene or the movement of event individuals outside of the EMS system toward a healthcare organization [hospital])
6. Contamination and decontamination
7. Capacity and surge capacity issues
8. Cooperation (between community and healthcare organizations)
9. Chaos and confusion with the failure or compromise of a system
10. Critical incident stress debriefing (providing necessary psychological support to first responders and individuals affected by the event)

This is the current situation, which provides an opportunity for emergency physicians as they seek to define their role and the role of emergency medicine in disaster management.

The Role of Hospitals in Disaster

Mary W. Chaffee and Neill S. Oster

INTRODUCTION

When the first rain began to fall in Houston, Texas, in June 2001, did hospital staff know they would soon be providing care for hundreds of patients without electrical power or running water in flooded hospital buildings?

On April 19, 1995, did the emergency department staff arriving for the day shift at 13 Oklahoma City hospitals know that a former soldier was driving a rented van filled with 4000 pounds of ammonium nitrate toward the Murrah Federal Building and that they would soon be faced with 324 bombing victims?

In 1984, did restaurant patrons in Wasco County, Ore., have any idea, as they selected food from salad bars, that they would soon be evaluated in hospitals for profuse, watery diarrhea from intentional food contamination by a religious cult?

In March 2003, did the 11 Toronto healthcare workers who were caring for patients with respiratory symptoms know they would soon become infected with severe acute respiratory syndrome (SARS)?

We can be quite certain that none of them knew. The capricious nature of disaster implies victims and responders are generally caught unaware.

But we do *know* some things. We *know* there will be hurricanes, typhoons, tornadoes, earthquakes, mudslides, fires, and blizzards this year. We *know* people will pick up firearms, make bombs, and inflict pain and suffering on others. We *know* there will be casualties from train accidents, cars crumpled in chain reactions, building collapses, and explosions. We *know* infectious diseases will do what they do best: spread, sicken, and kill. We *know* terrorists have not given up their violent assaults. We *know* there will be mental health symptoms in accident survivors and the caregivers who respond to their needs.

It is the *hospital*, at the heart of the health system, that will receive the injured, infected, bleeding, broken, and terrified from these events. We *know* the victims will seek life-saving care, comfort, and relief at hospitals, but many U.S. hospitals continue to prepare for disaster as though it will not happen to them.

Hospital Capacity in the United States

There are more than 5700 hospitals in the United States that form a diverse patchwork of healthcare services.

U.S. hospitals vary greatly by geographic location (urban, suburban, and rural); financial and management structure (for profit, not-for-profit, private, public); type of care (general medical services or specialty care, such as psychiatric or pediatric); and government affiliation (Department of Defense, Veterans Health Administration, or Public Health Service). Any of these hospitals may be called on to respond to the next disaster or may be the victim of a disaster. Many experts believe that these hospitals are not adequately prepared to respond effectively (Table 5-1).

HISTORICAL PERSPECTIVE

The Role of the Hospital in Society

The hospital was of little significance in American healthcare before the Civil War. Only 178 hospitals existed in 1873 when the first survey was conducted—a time when no proper gentleman or lady would venture into a hospital by choice.¹ The murky medical practices of the 1800s offered little that couldn't be found in homes, and physicians had little in their armamentarium to change the course of disease and injury. However, discovery and scientific advance changed that. Effective anesthesia, surgical antisepsis, antibiotics, the x-ray, and other advances turned the hospital into a place of comfort, hope, and healing. The 20th-century hospital became a sophisticated financial institution, the core of medical education, and the site of dazzling technological display. Medical advances offered aid not only to the chronically ill but offered hope to those who suffered acute trauma or medical or psychiatric emergency.

The Effect of Disaster on Hospitals

Past events illuminate the variety and complexity of demands placed on a hospital in a disaster:

- *Hurricane Katrina*. The flooding in the wake of Hurricane Katrina in 2005 left hospitals in greater New Orleans, Louisiana, and Mississippi in crisis. Patients and staff were trapped in facilities without essential services, resulting in the largest mass hospital evacuation in U.S. history.

TABLE 5-1 SNAPSHOT OF 2005 U.S. HOSPITAL CAPACITY*

Total U.S. Hospitals	5764
U.S. community hospitals	4845
U.S. federal government hospitals	239
Institutional hospitals (e.g., prisons, colleges)	23
Nonfederal psychiatric hospitals	477
Nonfederal long-term-care hospitals	180
Total staffed U.S. hospital beds	965,256
Staffed community hospital beds	813,307

*Source: American Hospital Association. Hospital statistics, 2005 edition. Available at: www.hospitalconnect.com/aha/resource_center/fastfacts/fast_facts_us_hospitals.html.

- *Floods caused by tropical storm Allison in Houston, Texas.* In June 2001, 3 feet of rain from tropical storm Allison fell in the Houston area, causing the flooding and complete disruption of services at the University of Texas Health Science Center and its clinical affiliate hospitals. One of the hospitals, Memorial Hermann Hospital, experienced failure of every hospital system. The main and emergency power generators and communications system failed and personnel could not come, go, or be reached. The water supply failed, and the sewer system stopped functioning. The vertical evacuation of 570 patients was conducted, and the hospital was closed for 38 days. The storm flooded an area not considered to be at risk.²
- *The Northridge, Calif., earthquake.* An earthquake struck Northridge on Jan. 17, 1994, damaging a number of area hospitals. Six hospitals evacuated patients immediately: four of these evacuated all inpatients, and two evacuated some. Five of the facilities evacuated the most severely ill first, but the sixth, fearing imminent structural collapse, evacuated the healthiest patients first to permit the evacuation of the largest number of patients in the shortest period. That facility moved 334 patients from buildings to open areas in two hours. All hospitals used improvised transport devices, including backboards, blankets, and mattresses.³
- *The 2001 World Trade Center bombing.* Bellevue Hospital, a level-1 trauma center in New York City, is approximately three miles from the World Trade Center. Ninety patients presented within the first five hours after the incident; a total of 194 were triaged and treated within the first 24 hours. Despite best efforts, the hospital lost track of patients, ran out of supplies, and struggled with coordination of physicians to ensure rest and safety.⁴ New York University Downtown Hospital, a few blocks from the disaster, received 350 patients within the first two hours of the World Trade Center attacks. Many patients arrived on foot.⁵ St. Vincent's Catholic Medical Center executed its disaster plan within minutes of the bombing, as they had done during the 1993 World Trade Center bombing. On Sept. 11, 2001, St. Vincent's Hospital

treated nearly 800 victims. Because St. Vincent's shared water lines with the World Trade Center and telecommunications lines were routed through the World Trade Center, function of these systems was affected. Crisis counseling, pastoral care, and mental health services were immediately made available for victims, families, rescue workers, and staff.⁶

- *The Oklahoma City Bombing.* After the explosion of a bomb at the Murrah Federal Building, 168 were killed and 700 were injured—388 with acute injuries. The first patients arrived in emergency departments within 15 minutes, and the hospitals within 1.5 miles of the blast site received the greatest number of victims.⁷
- *The Rhode Island nightclub fire.* On Feb. 20, 2003, fire erupted in a crowded nightclub in West Warwick, R.I. Almost 100 were killed immediately, and nearly 200 were injured. Kent County Hospital, a 350-bed community hospital 2 miles from the site of the fire, received 40 victims within an hour; 25 were rapidly intubated. The hospital ran out of critical supplies and ventilators and struggled with supporting family members, poor communications from the scene, and pain management.⁸ Ultimately, 16 hospitals in Rhode Island and Massachusetts received 196 burn victims; this included the Shriners Hospital for Children, which received and treated 16 adult victims.⁹

The potential impact of disaster is staggering. The release of 40 tons of methyl isocyanate from the Union Carbide factory in Bhopal, India, in December 1984 exposed more than 500,000 to the deadly gas and killed about 6000 in the first week after the release. In September 1987, workers scavenging a dismantled cancer clinic in Goiania, Brazil, took home a source containing cesium-137. They sold it to a junkman who showed the glowing item to friends and neighbors. Once radiation exposure victims presented to hospitals, and the release became well known, hospitals were overwhelmed. Although 250 were actually exposed and 28 showed signs of radiation sickness, 112,800 people were evaluated. When the Aum Shinri Kyo cult placed sarin on five trains in the Tokyo subway system on March 20, 1995, 4000 people made their own way to hospitals, 641 were transported by authorities, and 245 hospital staff and rescue personnel were contaminated due to poor or nonexistent decontamination procedures.¹⁰

Evolving Perspective on the Health System Role in Disasters

On Sept. 11, 2001, when U.S. hospitals and healthcare professionals were confronted with the worst attack on American soil, and again during the anthrax attacks along the Eastern Seaboard, individuals and organizations responded heroically. A powerful change in thinking, also called a *paradigm shift*, occurred after the terror attacks: the health system came to be viewed as a foundation of national security. Another perspective has changed as well. In the event of a disaster, Emergency Medical Services (EMS), police, and fire have long been recognized as first responders. However,

just recently, hospitals also have been designated as first responders—and first receivers.

The value of the hospital in national security has been increased, and hospitals are recognized as safe havens in communities, the public expects hospitals to be prepared to care for their needs, and the hospital is now recognized as a first responder in emergencies. However, hospitals remain significantly underprepared to respond as effectively as the public expects. Most importantly, preparedness is at direct odds with productivity. Daily operating requirements stretch most hospitals' resources. Allocating funds to improve emergency response capabilities that may never be used could be viewed as foolhardy. Community integration is now seen as necessary, but hospitals (other than those in networks or that are government facilities) have had few reasons to build healthy relationships with other hospitals in their communities. To meet the needs of communities in a disaster, business competitors must work as partners.

Public Expectations

Hospitals play a vital role in the health, social structure, and economic life of a community. Patients expect hospitals, and health system workers, to be available to provide care for them in all circumstances. A level of preparedness that was viewed as adequate in the past is no longer seen as acceptable. To be more highly prepared and to be able to respond effectively, hospitals must make substantial investment in equipment, training, facilities improvements, and supplies.¹¹ Hospitals depend on public trust; poor performance during a disaster could be financially crippling to a facility. Rubin¹² writes that hospitals are expected to handle whatever they receive and do it right the first time.

CURRENT PRACTICE

Sources of Hospital Vulnerability

Hospitals are vulnerable to the stresses of disaster responses due to a number of inherent characteristics:

- *Complexity of services:* Hospitals are facilities that provide healthcare but must also function as laundromats, hotels, office buildings, laboratories, restaurants, and warehouses.
- *Dependence on lifelines:* Hospitals are completely dependent on basic public services: water, sewer, power, medical gases, communications, fuel, and waste collection.
- *Hazardous materials:* The hospital environment contains toxic agents and poisonous liquids and gases.
- *Dangerous objects:* Heavy medical equipment, storage shelves, and supplies can fall or shift during an event such as an earthquake.¹³

Forces Influencing Preparedness

Multiple forces have placed hospitals in a precarious preparedness posture. The capacity of the health system

has been scaled down to a bare minimum to cut operating costs. Emergency departments are crowded with the uninsured and the underinsured who have no other access to care. The nursing workforce has withered, and physicians have left practice due to uncontrolled liability insurance costs.

Surge Capacity

Many hospitals determine their surge capacity by the number of patients they could comfortably care for using standard spaces, quality care standards, and additional teams of personnel to help. In reality, a disaster is not going to comply with the limits of hospital capacity. If 300 bombing victims arrive at a 50-bed community hospital, spaces will need to be converted and used that planners may have never imagined, such as chapels, hallways, and offices. Nurses accustomed to a certain nurse-to-patient ratio may find the ratio in a disaster much higher and have to adapt practice accordingly. Surge capacity must not be viewed only as the number of beds or spaces that can be allotted to care for patients, but it must include all supporting hospital services that are involved in patient care.

Critical Elements in Hospital Preparedness

If hospital services fail during a disaster, the hospital fails the population depending on it. The population includes not just the victims of the disaster, but the others presenting for needed care—women preparing to give birth, patients with chronic disease exacerbation, and children with lacerations that need sutures. A vital hospital emergency management program acts as an insurance policy that increases the chances of continued operations under difficult circumstances. An effective hospital emergency management program guides the development and execution of activities that mitigate, prepare for, respond to, and recover from incidents that disrupt the normal provision of care.¹⁴ The program should include the following components:

- *Emergency manager:* The emergency manager is the primary point of leadership in the development, improvement, exercise, and execution of the hospital's emergency management plan.
- *Emergency management plan:* The plan identifies the hospital's response to internal and external emergencies. Deliberate (advance) planning permits the development of strategies while the organization is not under pressure to react.
- *Executive leadership:* Hospital executive leadership charts the course for an organization. A hospital that lacks executive leadership committed to emergency preparedness will be significantly hampered in its efforts.
- *Strategic planning:* The hospital's strategic plan is the blueprint that guides all efforts to achieve its mission. It is critical that emergency management and preparedness efforts are woven into strategic planning.
- *Emergency management committee:* Extremely broad membership is desired to ensure all hospital

operations that will be stressed in a disaster are integrated and well prepared.

- **Hazard vulnerability analysis (HVA):** The HVA is a tool used to assess the risks in a specific environment. The emergency management plan can be tailored to address the hazards most likely to affect hospital operations.
- **Vulnerability analysis:** Every aspect of hospital operations that will be depended on in a disaster should be assessed to determine whether there are weaknesses present that fail when stressed. Hospitals in the U.S. Navy Medical Department and a number of civilian hospitals in New York have had their level of preparedness assessed using the Hospital Emergency Analysis Tool (HEAT). The HEAT examines more than 230 factors that contribute to effective emergency preparedness and response. After the systematic analysis by a team of experts, the hospital receives an after-action report that documents strengths and weaknesses and permits the development of a strategic plan to improve preparedness.¹⁵
- **Staff training, exercise, and continuous improvement:** The Joint Commission on Accreditation of Healthcare Organizations requires hospital staff members involved in the execution of the emergency management plan to receive orientation and education relative to their role in an emergency. Exercise of the emergency plan is also required. Lessons learned should be integrated into plans to continuously revise them.

Hospital Preparedness Philosophy

A commitment to the following philosophies will enhance hospital emergency preparedness:

- **Imagine the unimaginable:** When flood waters rise in a community, when a tornado touches down and demolishes an elementary school, when a disgruntled hospital employee opens fire with an automatic weapon in the emergency department, when a passing train derailed and spills toxic chemicals, or when a wild-fire closes in, it is too late to update an old plan, train staff to respond effectively, check phone numbers, and stock disaster supplies. Disaster complacency—believing a problem won't happen to you or your hospital—is a significant threat to effective planning and response.
- **Protect the staff:** Only a true obsession with self-protection will ensure that staff members are not injured or become ill during disaster response. Adequate stockpiles of gloves, masks, and other equipment must be available, along with training and leadership commitment to self-protection policies.
- **Build in redundancy:** Expect the primary plan to fail and build in alternatives to every emergency measure.
- **Rely on standard procedures whenever possible:** People perform best in unusual situations when they perform activities that closely mirror what they do under normal conditions.
- **Maintain records:** Patient care records are critical to obtaining reimbursement for disaster care provided.

- **Plan to degrade services:** Normal levels of services cannot be maintained during disaster response. Identify services, such as elective surgery, that can be temporarily curtailed or minimized so that personnel and resources can be reassigned.

The Federal Role in Hospital Emergency Preparedness and Response

The federal government has implemented programs to augment local and state capabilities when they are overwhelmed.

The National Disaster Medical System

The United States has a well-established emergency medical safety net: the National Disaster Medical System (NDMS). The NDMS has two primary capabilities designed to enhance disaster medical response. The first is specialized disaster response teams who augment the medical emergency response at the site of disaster. The second NDMS capability is a plan to share the inpatient bed capacity of the civilian and federal health systems in the event either system is overwhelmed with patients requiring inpatient care.

NDMS federal coordinating centers (FCCs) play a regional role in maintaining a supply of NDMS hospital members and providing training and exercises. When the NDMS is activated, FCCs coordinate patient reception and distribution of patients being evacuated.

Hospitals enter into a voluntary agreement to participate in the NDMS. They must be accredited and generally have more than 100 beds. The agreement commits a hospital to provide a certain number of acute care beds to NDMS patients; however, it is recognized that hospitals may or may not be able to provide the agreed-upon number of beds. Hospitals that receive NDMS patients are reimbursed for care by the federal government.¹⁶

The Strategic National Stockpile

The Strategic National Stockpile (SNS) was established in 1999 as the National Pharmaceutical Stockpile. It is now managed by the U.S. Department of Homeland Security and serves as a national repository of antibiotics, chemical antidotes, antitoxins, intravenous therapy, airway management equipment, and medical/surgical items. The stockpile is designed to supplement local agencies that are overwhelmed by a health emergency.

The Noble Training Center

The Noble Training Center in Anniston, Ala., (on the site of the former Fort McClellan army base) is the only hospital facility in the United States that trains health-care professionals in disaster preparedness and response. The Department of Homeland Security operates the Noble Training Center, which offers a variety of training programs, including one for hospital leadership. More

information is available online at: <http://training.fema.gov/emiweb/ntc/>.

Even though the federal government has many emergency response assets that can help in the response to an emergency, experience has shown that hospitals must be prepared to be self-sufficient for 24 to 72 hours after an event.¹⁴

Critical Elements in Hospital Disaster Preparedness

A comprehensive hospital emergency management program must address a number of critical elements to adequately protect patients and staff and permit the facility to continue to operate. These are discussed in the following.

Incident Command

Just as one team leader is necessary for a controlled response to a cardiac arrest, an organized approach is essential to a successful hospital-wide emergency response. The Hospital Emergency Incident Command System (HEICS) is designed to provide that coordination. Developed and tested in Orange County, Calif., in 1992, it provides structure to response. HEICS uses:

- A reproducible, predictable chain of command
- A flexible organizational design that can be scaled to the scope of the problem
- Checklists for each position to simplify response and carefully define each task
- A common language that permits communication with outside agencies

Emergency Operations Center (EOC)

The EOC will serve as the command post for operations during an emergency response. It should be fully operational and integrated into local and county emergency operations (Box 5-1).

Exercises, Drills, and Training

Hospital disaster drills have often been treated as annoyances and are planned in ways to render them futile. Exercises are generally announced (unlike actual events), planned during regular business hours, and rarely include all hospital operations that will be affected by an actual event. Hospitals are encouraged to drill individual units—frequently and during nights and weekends—and then build up to full, functional exercises involving management of moulaged “casualties.” Community participation is critical to identify elements that work or that need fine-tuning. Only through exercise will the plan be adequately stressed so that failure points are identified.

Essential Services and Facilities Engineering

The facility’s structural integrity and essential services are an often overlooked part of preparedness. In 2003 a

BOX 5-1 RECOMMENDED EQUIPMENT AND SUPPLIES FOR A HOSPITAL EOC

Location

- Secure interior space; windows not desirable
- Alternative, equipped space in distant part of complex or building in the event the primary EOC is damaged or disabled

Equipment

- Incident command gear to identify EOC staff (vests, ball caps)
- Computers with Internet access
- Dedicated telephone lines
- Communications-on-wheels (COWS)
- Two-way communications (400 MHz, 800 MHz)
- Fax
- Television with cable access
- Refrigerator
- Radio
- Bull horns
- Barrier tape
- Flashlights and batteries
- Back-up power generator
- Chalk board, dry-erase board, or other means of communicating to EOC team member

Information

- Hospital emergency management plan
- Reference materials (emergency response, clinical references, hazardous materials)
- Emergency reference contact numbers/e-mail addresses/fax numbers for local emergency response agencies (police, fire, emergency medical services, office of emergency management, department of health)
- Emergency contact information for national resources, including Centers for Disease Control and Prevention (CDC), Radiation Emergency Assistance Center/Training Site (REAC/TS), Agency for Toxic Substances and Disease Registry (ATSDR), Environmental Protection Agency (EPA), and National Response Center
- Staff notification information (phone contact numbers)
- Memoranda of understanding/agreement (MOU/MOA) with agencies and vendors
- Local and regional maps that include utility stations, hyperbaric capability, emergency medical services, police departments, fire stations, burn units, and other critical infrastructure

major power blackout in the northeastern United States and Canada demonstrated the impact of the loss electrical services. It is recommended that every hospital:

- Possess emergency power generating capacity for 3 to 4 days’ duration
- Perform annual load testing on the generator(s)
- Maintain the water supply and an alternative water supply in secure areas in sufficient quantity to support all services (sanitation, hygiene, laundry) for 3 to 4 days
- Maintain medical gases in a secure location and have a 3- to 4-day supply for the hospital
- Configure the heating-ventilation-air conditioning

(HVAC) system so that it can be shut down and, ideally, so that specific zones can be manipulated to control airflow in the building in case of contamination

- Maintain a fuel source for full-load demand for 3 to 4 days' duration
- Develop a plan for the management and disposal of increased volumes of contaminated waste

Physical Security

Maintaining the physical security of the structure is important on a daily basis but becomes more of a challenge during a disaster. To ensure that the environment remains safe, egress must be controlled. Additional elements of the physical security plan should include the following:

- A security force with full-time security responsibilities; the force should have undergone criminal background checks and professional law enforcement training.
- All entrances and exits should be controlled, monitored, and capable of being locked.
- The hospital should be able to perform perimeter security protection ("lockdown") within minutes of notification.
- Hospital staff should be trained and drilled on the performance of lockdown.
- Hospital leadership should know what triggers the execution of a lockdown procedure.
- A plan should exist for supplementing security staff in a disaster.

Situation Report (Rapid Needs Assessment)

It is critical that a hospital be able to rapidly assess the impact of a disaster on its operations and communicate the status to leadership in a situation report (often referred to as a "sitrep"), or a rapid needs assessment (RAN). The assessment should, at a minimum, include the following:

- The extent and magnitude of the disaster and the scope and nature of casualties
- The status of operations and any disrupted critical services
- The impact of disruptions on operations and the ability to sustain operations¹⁷

Staff Notification

Hospital staff must be able to receive timely and accurate notifications in a disaster, including when and where to report and for how long and other essential information. Contact information for all staff members must be continuously updated and tested. Additionally, the facility must be able to receive warnings and notifications from external agencies and be able to send warnings.

Triage System

Triage is performed daily in emergency departments, where the most critical are treated first. But during a dis-

aster, triage procedures must adapt to become like what is used on the battlefield, where the greatest good is offered to the greatest number. Multiple disaster triage systems exist, including START (simple triage and rapid treatment), ID-ME (immediate, delayed, minimal, expectant), and MASS (move, assess, sort, and send). It is important that a hospital use a system that is consistent with what is being used by services delivering patients to the facility. Whatever system is selected, there must be predisaster training and exercises.

Alternative Triage Area

When casualties present to an emergency department in numbers that overwhelm the facility, an alternative area must be available to manage overflow. The alternative triage area should be lit so that it can be used at night, weatherproofed, and temperature-controlled.

Risk Communications and Media Management Plan

A plan for working with the media will be needed. It is not recommended that media personnel be permitted access to a hospital during a disaster, but rather be provided regular, factual updates on activities and the status of the facility at a predetermined meeting place. Risk communications involve using credible experts to deliver carefully worded messages to communicate most effectively in a high-stress, low-trust environment, such as a disaster. Preparing hospital leaders in risk communications principles will ensure that they are able to communicate effectively to the public via the media.

Disaster Mental Health Services

There is conflicting evidence about the value of certain types of mental health services in the wake of disaster, but it is clear that every disaster creates emotional trauma victims. Primary victims are those who have been directly affected by the disaster. Secondary victims are rescue workers in whom symptoms develop, and tertiary victims are relatives, friends, and others who have been affected. The critical incident disrupts a victim's sense of control as daily life is abruptly changed.¹⁸ Hospitals must plan for providing mental health services to disaster victims but must also consider the needs—acute and long-term—of the hospital staff who attempt to respond to an overwhelming event. It is recommended that hospitals have trained crisis intervention teams that are well integrated into the emergency management plan.

Evidence and Crime Scene Management

In the event of an intentional act that results in mass casualties, not only must a hospital care for the victims, but it has a critical role in bringing perpetrators to justice. Hospital staff members require training in proper management of potential evidence—in both collection and preservation. Evidence collection containers, including 50-gallon drums for patient decontamination

run-off, should be available as well as bags to preserve other types of evidence. Law enforcement agencies and forensic departments can provide training and guidance. Staff members should be familiar with and follow procedures for maintaining chain of custody for evidence that is collected during patient care activities.

Food Services

A disaster will place significant demands on the food service system of a hospital. The adequacy of food supplies for patients and staff should be evaluated. Because a hospital may need to be self-sufficient for several days in a disaster, a 3- to 4-day supply of food products is advisable. Food service personnel should be included in disaster exercises.

Role of Volunteers

Volunteers may or may not be of assistance, depending on their relationship with the hospital and their background. A volunteer pool that consists of individuals who serve regularly at the facility, are familiar with standard procedures, and participate in exercises can add valuable manpower to a disaster response effort. On the other hand, disasters will draw volunteers who wish to assist, a phenomenon known as “convergent volunteerism,” in which unexpected and uninvited healthcare workers arrive and wish to render assistance at a large-scale incident.¹⁹ These “freelancers” may cause problems or may even be impostors.

Disaster Supplies

Despite “just-in-time” supply schedules and empty warehouses, hospitals should maintain dedicated disaster supplies and arrangements for rapid resupply in the event of a disaster. Disaster response will rapidly deplete critical supplies—administrative as well as clinical. Conducting realistic exercises will help with the determination of the adequacy of stock and can be done without opening actual supplies so they can be restocked. Disaster supplies can be rotated into the daily-use stream to ensure stock does not expire.

PITFALLS

Experience with disasters has demonstrated a number of predictable pitfalls that occur in hospital disaster response.

Distribution of Casualties

Because immediate on-scene control of a disaster is chaotic and communication is often problematic, patients will present to the closest hospital available. This often leaves other nearby facilities with capacity and personnel that go unused.

Personal Protective Equipment

Hospital personnel must be experts in protecting themselves, or they will become part of the problem and fur-

ther stress the facility. Some controversy exists over the level of protection needed in certain environments, but it is clear that masks (N95) and gloves (latex or nonlatex) will prevent transmission of biological agents.

Communications

Communications failure has often been identified as a predictable failure in disaster response. Hospitals need to examine both internal communications systems (with staff and patients) and with external agencies. Multiple layers of redundancy are essential to deal with expected failures and include the use of 800-mHz radios, dedicated trunk lines in the emergency operations center, two-way communications for hospital units and essential personnel, communications-on-wheels (COWS), and access to amateur radio (Ham) operators. The last resort is using runners who carry messages.

Emergency Patient Decontamination

Hospitals must be able to identify and decontaminate patients who have been exposed to radiation or a compound that poses a threat to the patient’s health and the safety of the facility. If the hospital depends on an external agency or has decontamination equipment that requires time to set up, an immediate alternative must be in place, such as a hose and hose bib outside of the emergency department. Consideration should be given to patient privacy, managing patient valuables and clothes, and handling weapons brought into the hospital. A trained, exercised, and well-equipped team will be the foundation of successful efforts.

Child Care

Hospitals will benefit from having a plan to care for children and other dependents of staff. In a disaster, staff will be called on to work extended hours, and usual family care arrangements may be unavailable.

Patient Admission, Identification, and Tracking

The creation of emergency patient admission packs that are maintained with disaster equipment will facilitate the admission of a large number of patients. If an automated patient tracking system is used, a back-up manual system should be available. All systems should be able to manage unidentified (John and Jane Doe) patients.

Mass Fatalities

Many hospitals have wholly inadequate or nonexistent plans to manage mass fatalities. Morgue space is generally limited in most facilities, so additional surge capacity must be identified in advance. Arrangements for refrigerated storage trucks, refrigerator space, and other alternatives, including ice rinks, should be addressed with socially sensitive plans. Complex cultural and religious issues may come into play in the event that there are contaminated remains and should be examined in advance.

Disaster Pharmaceuticals

Emergency drugs must be available at the point of care. Often they are secured in pharmacy departments or warehouses, resulting in precious minutes of life-saving time being lost as personnel try to locate and obtain critical medications. In addition to drugs needed to respond quickly to nerve agents and other emergency situations, stockpiles of antibiotics should be maintained to provide prophylaxis to patients and staff.

CONCLUSION

In a disaster, patients converge on the place they know they can obtain care—the hospital—and they arrive using any means possible. Furthermore, with the victims of disaster, come their families, loved ones, and the media—all who have very important needs that must be addressed. Hospitals can no longer approach disaster planning with a minimalist attitude that relies heavily on luck and belief that it will be someplace else that gets hit by the disaster.

The hospital that received the most patients from the Rhode Island nightclub fire got lucky—the victims began arriving during a change of shift so there were two shifts of nursing staff available. However, the hospital also attributes its effective response to having drilled critical departments and procedures.

Emergency planning is the backbone of preparedness, but events will occur in each disaster that demand creative responses under pressure. This ability to respond flexibly is known as *planned innovation*. Good plans will use general “all hazards” templates for disaster management but will permit independent initiative and a tailored response to a specific situation.²⁰

The U.S. health system appears to be emerging from the dark ages of emergency planning. A minimalist attitude of preparedness was acceptable in the past despite the regular occurrence of natural disasters. The threat of terrorism and the resulting health system impact have stimulated investment in research, a resurgence of disaster training in nursing and medical schools, and visionary projects such as ER One. ER One is a national prototype for a next-generation emergency department. Located in Washington, D.C., it is developing new approaches to the medical consequences of terrorist attacks, natural disasters, and emerging illnesses. More information is available online at: <http://er1.org>.

The next phase of hospital emergency management will be a renaissance if creative planning prevails over naysayers, if resources are applied to priority preparedness activities, and if healthcare leaders are committed to ensuring that all who depend on hospitals will receive the care they need in a disaster (Box 5-2).

Complex Emergencies

Frederick M. Burkle, Jr. and P. Gregg Greenough

Since the end of the Cold War, 95% of all major conflicts have been internal nation-state wars. These are commonly referred to as *complex emergencies (CEs)* because of the myriad political, sociocultural, and economic factors that provoke them.

Zwi and Ugalde¹ defined CEs as “situations in which the capacity to sustain livelihood and life are threatened primarily by political factors and, in particular, by high levels of violence.” National disruption resulting from conflict and war has occurred this last decade in nation-states such as Liberia, Somalia, Rwanda, Angola, the former Yugoslavia, the province of Kosovo, East Timor, and Iraq. Unfortunately, CEs represent catastrophic public health emergencies that often develop into a continuum of protracted social conflict.

MAJOR CHARACTERISTICS

The defining characteristics of CEs include the following:

- CEs have existed for many years; however, during the last two decades, they have become the most common type of human-generated disasters.² Currently there are 35 countries at risk of serious conflict, 11 of which are near collapse. Primarily because of unresolved war and conflict, worldwide hunger has climbed 18%, leaving more than 850 million people without food for basic health.³ Conflict has degraded the agricultural and public health infrastructures during the past decade, directly increasing the toll of civilian morbidity and mortality.
- CE victims commonly suffer from social, economic, and gender inequities; poverty; injustices; cultural and religious persecutions; ignorance; racism; oppression; religious fundamentalism; and other lethal factors that contribute to internal strife among varied ethnic, tribal, and religious groups. All adversely affect the public health and the access to and availability of healthcare.
- The majority of victims are civilians, with mortality and morbidity largely among vulnerable and unprotected children, women, the elderly, and the disabled. During the Cold War, one-half of all conflict-related deaths were among civilians. Civilians in CEs account for 90% of all war-related deaths, and more children than soldiers, about 2 million through 1993, have died as a result of internal civil strife.⁴ Genocide and other wanton violations of the Geneva Conventions have contributed to the high violence rates directed at civilians.
- There is a linear relationship between mortality of children younger than 5 years (per 1000) and the percentage of nations engaged in armed conflict. The worst conditions and highest mortality rates are recorded among orphaned and unaccompanied children who frequently fall through the cracks of the humanitarian response effort and who require parental or surrogate adults for the distribution of critical aid. In large, rapidly forming refugee camps, the most vulnerable can easily be lost among the masses and go unrecognized by those operating fledgling humanitarian relief efforts.
- CEs must be understood and managed in the context of politics. Intervention, relief, success, and failure of CEs are dependent on politics and outside military actions to end, or at least contain, the violence. During the 1990s, the world community, with varying success, responded to the more publicized CEs (Iraqi Kurds fleeing the Saddam regime to northern Iraq, severe hunger in rebel-ravaged Somalia, the ethnic and religious cleansing in the Balkans, and the political plight of East Timor). However, outside assistance has been limited or avoided in other conflicts (mass slaughter in Rwanda and the Democratic Republic of the Congo and the unrelenting conflict in Sudan). With minority and ethnic groups at risk of extinction, the customs, skills, and the very foundations of health and public health refinements that have defined their cultures have ceased to exist.
- Healthcare professionals face major challenges just to decrease the immediate mortality and morbidity resulting from communicable disease, trauma, and the dire health consequences of infrastructure losses in water, sanitation, shelter, and food.
- The targeting of healthcare providers and medical neutrality is a consistent feature of CEs. Hospitals are predictably the first to be destroyed and the last to be rehabilitated.⁵ Therapeutic feeding centers for starving infants and primary health centers are commonly

destroyed and looted, and female and child patients are slain in their beds. Warring factions have purposely politicized health and with it have summarily executed or detained physicians and nurses to foment fear. As political violence increases, access and availability to healthcare diminishes.¹

HISTORICAL PERSPECTIVE

A wealth of evidence has accumulated for more than 25 years on the massive effect of war on health. Field epidemiological research has defined the health and public health characteristics of CEs.⁶ Data have further demonstrated a consistent negative association between violent conflict and health outcome indicators (life expectancy, infant mortality rates, and immunization rates).^{1,7} Additional studies have confirmed the negative impact of landmines and sanctions on the health of children and that government instability and societal decline are the complex catalysts whereby controls on tuberculosis, malaria, and human immunodeficiency virus (HIV) become unchecked. Between 1990 and 1995, the disease burden of war equaled that of homicide and suicide when measured in disability adjusted life years (DALYs). Further, data analyses now suggest a trend in which the ranking of lives lost from the total consequences of war and conflict would move from the top 20 causes of disability, where it is now, to the top 10 by the year 2010.⁸

Populations suffer both direct and indirect effects of conflict. Direct effects include injuries, deaths and disabilities, human rights and international humanitarian law abuses, and psychological stress. Indirect effects actually contribute to the majority of mortality and morbidity due to population displacement, disruption of food supplies, and destroyed health facilities and public health infrastructure. At least three epidemiological models exist that may guide the current practice of the humanitarian response effort.

EPIDEMIOLOGICAL MODELS

Developing Country Model

The health profile of countries in Africa and Asia during the acute phase of a conflict or war is usually identified by moderate or severe malnutrition, outbreaks of communicable diseases, or often both. The most common CEs of the past two decades have involved famine and forced migration in developing countries. Since the 1980s, few famines have occurred that were not human induced, and many famines catalyzed the onset of CEs.⁴

The most severe consequences of population displacement have occurred during the acute phase, when relief efforts have not yet begun or are still in the early stages.⁶ Refugees (populations that cross borders) and internally displaced populations have experienced high mortality rates during the period immediately after their migration. Internally displaced populations do not enjoy the immediate protections against persecution and human rights abuse under international law that are

afforded to refugees by the UNHCR (United Nations High Commissioner for Refugees). Internally displaced populations must fend for themselves without benefit of basic healthcare services, food, water, or sanitation. Stripped from their supportive infrastructure, refugees suffer mortality rates that are 7 to 10 times higher than those for the baseline indigenous populations. In the refugee camps at Goma, Congo, the crude mortality rates exceeded 60 times those of the baseline population.⁹

The health consequences are both directly and indirectly related to the conflict itself.⁴ Three-fourths of all epidemics of the last decade took place in CEs. Epidemiological indicators show high crude mortality rates and, if disaggregated, demonstrate the vulnerability among the populations as to age (children younger than 5 years and the elderly) and gender (women and female-headed households). For instance, high case fatality rates were common among malnourished children in Somalia, with measles contributing to between 50% and 81% of deaths.^{4,10,11}

Developed Country Model

Countries such as Iraq, the former Yugoslavia, Macedonia, and Kosovo had relatively healthy populations with demographic profiles similar to those of Western countries before the onset of internal conflict. In these places, the few epidemics and low prevalence of malnutrition among children and infants were superseded by undernutrition and chronic diseases among the elderly who could not flee the conflict or were unable to access healthcare. In these settings, war-related trauma from advanced weaponry contributed to the primary cause of mortality. Children, adolescents, and pregnant women were specific targets in Yugoslavia, with more than 3000 children killed by snipers alone. Rape and traumatic exposures commonly contributed to psychological morbidity.¹²

Chronic or Smoldering Country Model

Both Haiti and Sudan have unique problems related to long-standing conflict and unrest that prevent progress in health, healthcare delivery and access, disease prevention, and education. Except for high rates of HIV/AIDS, Haiti's health profile in disease is representative of one that was last seen in the United States in the early 1900s. Massive deforestation has led to severe environmental collapse that has contributed inextricably to chronic health and infrastructure loss.^{13,14} Haiti is representative of a smoldering country model that is suffering both an acute emergency situation as well as ongoing severe development problems. It is a dilemma to know where the assistance should be placed to do the most good. Some would rightly argue that without attention first to critical development priorities, acute emergency situations will continue to worsen. Sudan has experienced war since 1955, and as such, its children grow up chronically malnourished and know only a culture of violence with little access to healthcare and education. Reproductive health is an unknown luxury, and most healthcare must be imported.

EVOLUTION OF INTERVENTION

Pugh¹⁵ describes evolutionary phases of intervention seen during the 1990s. Initially, humanitarian assistance was believed to be all that was needed to meet the demands of what were considered temporary post-Cold War conflicts. By the mid-1990s, it was clear that CEs were more dangerous, longer lasting, and complex than first thought.

The humanitarian response was first dominated by international relief organizations, which based their presence on neutrality and impartiality protected under international treaties and covenants such as the Geneva Conventions. If and when military forces became involved, they did so under the rubric of ensuring relief security, which in places such as Somalia had been severely compromised by undisciplined rebel groups who had no knowledge about protections afforded to relief workers under the Geneva Conventions.

Intervention, relief, and the successes and failures of CE interventions depend on politics and the political action of many countries, agencies, and organizations. For both the United Nations (UN) and Western powers, political action is translated as “military action.” In the early 1990s, the UN response consisted of deploying peacekeeping forces under Chapter VI of the UN Charter to help quell the conflict and provide some semblance of security for the intervening UN agencies and international relief organizations (IROs). These loosely defined civil-military relationships over time proved problematic. Many in the humanitarian community considered military involvement dangerous and unnecessary because a foreign, primarily Western, military presence threatened the neutral status of *all* expatriate workers. In these civil-military “interventions” both sides were ambivalent about their roles, cooperation, and under what security criteria the military should leave (the so-called exit strategy or end state that is constantly debated within the humanitarian and military-political communities).

It was soon recognized that sustained development and long-term improvements would never occur without a political solution. The “humanitarian imperative” that drove the initial relief assistance was threatened by naysayers and others who strongly believed that assistance without a clear political road map to mitigate the causes of the conflict was self-defeating. By the mid-1990s, studies exposed a parallel crisis in humanitarian protection. The humanitarian community was not protecting those that needed protection. The relief agencies, called on to implement assistance programs, were inconsistent and lacked professionalism. In addition, despite growing needs worldwide for intervention, both donors and governments were allocating less and less to fund the needed resources. The frustration during the 1990s was characterized over time by healthcare providers meeting the challenge to save lives, only to find the situation sliding back into crisis.¹⁵

By the turn of the century, studies revealed alarming data on mortality from intentional violence and banditry against humanitarian relief agencies and peacekeeping forces. One study¹⁶ found that 68%, or 253 deaths, of

375 deaths among staff of certain relief agencies and UN peacekeeping forces between 1985 and 1998 were a result of intentional violence. Of 52 deaths among staff for the International Committee of the Red Cross (ICRC) and the International Federation of Red Cross and Red Crescent societies, 77% were a result of intentional violence.¹⁶

These events contributed to the decision to replace UN peacekeeping forces with peace enforcement troops. The peacekeeping forces had been deployed by the Security Council under UN Charter Chapter VI, which lacked the military resources and legal mandate to quell the violence. With the new method, under Chapter VII, peace enforcement troops have the resources to cease the violence required to protect civilians before a peace agreement is in place. This process of moving from peacekeeping to peace enforcement was slow, taking three years and 33 new Security Council resolutions to complete. All UN military interventions have been authorized under Chapter VII since its inception.¹⁷

Encouragingly, relief organizations found common ground for collaboration and cooperation in projects, programs, education, training, and decision-making. This common ground catalyzed the relationship between health and human rights and the defining of the “rights discourse,” which declares that victims have the *right* to humanitarian assistance and that nongovernment organizations (NGOs) and UN agencies have the *duty* to provide assistance. This common ground process also spurred the argument for a consistent framework of standards of care and benchmarks for professionalism within the ranks of the relief community.

In the midst of the chaos of CEs, healthcare professionals have taken on roles, other than that of providers, to negotiate and mediate with and cajole the warring factions to spare the health infrastructure from total annihilation. In doing so, negotiation and mediation with warring factions and rogue regimes have become increasingly necessary to maintain viable health programs threatened by political violence. This increasing presence of healthcare providers in the “political process” as decision-makers in conflict resolution is not always a comfortable role. Rather, these interventions could be fraught with personal risks and seeming violations of an organization’s impartiality and neutrality strictly defined under existing covenants. In taking on these roles, healthcare providers have been instrumental in developing unique solutions through negotiating “immunization days” with rebel groups and delineating “tranquility zones,” where vulnerable groups are isolated from the surrounding fighting.

CURRENT PRACTICE

Multinational Model Response

It is not uncommon for NGOs and other relief organizations to be established in a country in conflict long before the violence garners the attention of the international community. The larger multinational humanitarian response begins with a decision by the international community to intervene, usually because of increasing

violence and the migration of refugees across the borders into neighboring nations. This process comes after weeks and often months of debate within the UN Security Council before a resolution is passed that directs the scope of the humanitarian assistance and defines the actors who will participate. Since the major reason for intervention is to cease the violence that leads to health consequences, a UN resolution will first define the requirements of peace enforcement troops authorized under Chapter VII of the UN Charter. These peace-enforcement troops are needed to end the violence and abuses of international law and human rights, to provide a protective environment that allows for assistance to decrease mortality and morbidity, and to ensure a secure environment in which IROs can function. Diplomatic assets are used to develop peace accords and agreements that must be in place before the peace enforcement troops are redeployed and replaced by UN peacekeeping forces, who function to maintain the peace (under Chapter VI of the UN Charter).

Humanitarian assistance usually comes from assets contributed by the UN Office of the Coordinator for Humanitarian Assistance (OCHA) and UN agencies such as the World Food Program (WFP), World Health Organization (WHO), and the UN Children's Fund (UNICEF); the Red Cross Movement; NGOs; and donor agencies that primarily represent industrialized nations' governments, such as the U.S. Agency for International Development (USAID), the Canadian International Development Agency (CIDA), and Japan International Cooperation Agency (JICA).

The multiagency response to CEs grew rapidly in the decade of the 1990s. NGOs assumed increasingly more responsibilities for governments and international organizations by implementing major relief and assistance programs for vulnerable civilian refugees and displaced populations. In 1991, NGOs numbered 28 in northern Iraq; by 1995 in Haiti, there were more than 710 NGOs.

Health Assessment

The humanitarian community (international organizations, NGOs, private government organizations, and peacekeeping militaries) has a professional obligation to base assistance on the best evidence available.¹⁸ This supposition is the cornerstone of the concept of evidence-based healthcare.

The need and demand for healthcare in CEs increases at a rate determined, in part, by the rate at which public health infrastructure is destroyed and the moral integrity of governance disappears. Initially, healthcare needs may be greater than the rate at which resources are being made available.¹⁹ Historically, response activities in CEs have often been ineffective because of the poor quality of information available as well as the manner in which an assessment was conducted. Assessment and assistance are often hampered by organizational problems and lack of personnel, medical records, and financial resources.²⁰ Epidemiological methods established for situations in which there are restricted resources use a simpler method of statistical analysis, which is known as a *rapid assessment*²⁰ and is sometimes referred to as

a "quick and dirty" assessment.²¹ The initial assessment by an experienced interdisciplinary team must be carried out as soon as it is clear that an emergency exists.

During the decade of the 1990s, both health and nutritional assessments, despite being performed rapidly and under difficult situations and restraints, gained a reputation for quality. With critical advances in indicator identification, epidemiological analysis, data retrieval technologies, and education and training of relief personnel, health and nutritional assessments have continued to improve as an art and science.

Data collection commences before the field assessment and originates from existing country profiles, maps, census data, previous demographic and health surveys, early warning system tools, and previous or ongoing in-country assessments.²² Additional data may come from overflights and satellite imagery; these are especially useful in tracking refugee migration. Background health information is gleaned from previous reports inherent to organizations such as WHO, the Disaster Epidemiology Research Center in Belgium, the European Expert Group in Practical Epidemiology (EpiCentre), and the Centers for Disease Control and Prevention's (CDC) *Mortality and Morbidity Weekly Report (MMWR)* publications. This information includes, but is not restricted to, baseline data on the following^{4,23-25}:

- Endemic diseases
- Mortality rates

Assessment documents are available that provide detailed checklists, information on the principles of an assessment, planning techniques, methods, and forms.

Use of an evidence-based approach makes it possible for decision-makers (policy, operational, and field level) to differentiate the needs of the population, the resources available, and the costs of any decision. An evidence-based approach helps one to differentiate between what is supported by evidence and that which is made on an unsubstantiated assertion. Health assessments today are expected to be reliable and valid and, as such, are inextricably linked to the analysis of specific performance and outcome indicators, region- and disaster-specific epidemiological studies, and measures of effectiveness.²⁶ Assessment in one form or another never stops.^{25,27*}

The assessment tool used can vary depending on the phase of the CE. The rapid health assessment of a CE concentrates on the needs of relief managers and decision-makers to obtain timely and accurate data necessary to rationally allocate available resources according to the emergency situation. Rapid assessment stimulates the development of more organized and focused surveys and the longer-lasting surveillance system, as well as a

*A full account of the assessment process can be found in: Burkle FM. Evidence-based health assessment process in complex emergencies. In: Cahill KM, ed. *Emergency Relief Operations*. New York: Fordham University Press and The Center for International Health and Cooperation; 2003.

health information system (HIS). The HIS facilitates the collection of demographic and vital statistics data, administration of a disease surveillance system, regular monitoring of hospital and clinic discharge diagnoses, and investigation of disease outbreaks.²⁸ How rapidly an HIS can be implemented is often used as a measure of efficiency and effectiveness of the relief effort.

During the early 1990s, response initiatives suffered because of poor and inconsistent humanitarian response and lack of assessment standardization. By the late 1990s, WHO rapid assessment protocols²³ and the Humanitarian Charter and Minimum Standards (SPHERE Project) provided the needed standardization guidelines to assess and assist in water supply and sanitation, nutrition, food aid, shelter and site planning, and health services.²⁴ The Sphere Project's Humanitarian Charter describes the core principles that govern humanitarian action and defines the legal responsibilities of states and parties in conflict to guarantee the right to assistance and protection.¹³ When states are unable to respond to a CE, they are obliged to allow the intervention of humanitarian organizations, which in itself begins with an assessment.

The concept of *excess deaths* is a critical epidemiological tool, especially in areas where there is conflict and where population movements are high. In war-affected areas of the eastern Democratic Republic of Congo (largely inaccessible to aid organizations and assessments because of insecurity),²⁹ the ongoing fighting drove hundreds of thousands of internally displaced people into forests, jungles, and other remote areas where they had no food, medicine, or shelter. Health systems and basic environmental public health infrastructure were destroyed. An epidemiological assessment was conducted, at considerable risk to the assessment team, of 11 mortality surveys in five provinces throughout eastern Congo. Results determined that over a 32-month period, approximately 2.5 million excess deaths (deaths greater than expected during the period studied) had occurred due to the conflict in that country. Previous reports had documented that approximately 100,000 people had died as a result of war.²⁹ The assessment revealed that the war casualties were not limited to victims of violence, but rather that 90% of the deaths were attributed to infectious diseases (e.g., malaria, diarrheal diseases) and other nonviolent causes (e.g., malnutrition) directly or indirectly related to the environmental disruptions. The destruction of the region's health infrastructure and lack of regional security meant that the vast majority of the population had minimal access to medical and public health services, making them more prone to disease. In addition, this assessment provided the only evidence that a humanitarian crisis of "staggering proportions" existed.²⁹ The assessment demonstrated the critical importance of how an epidemiological approach to an assessment can be used to document the denial of human rights associated with a lack of access to medical care, basic public health, and environmental services. Even though the study lacked the empirical scrutiny guaranteed with exact numbers, the assessment did reveal that a massive international response was indicated.

Health Interventions

All health and nonhealth interventions that support public health needs in CEs are determined by rapid assessments, focused surveys, and surveillance. Poor surveillance design, at all three levels (rapid assessment, surveys, and surveillance) will lead to a predictable resurgence of disease and public health disruption. If survey indicators and surveillance methodologies are incomplete or inaccurate, the ability to monitor the sensitive relationships between health, nutrition and environmental indicators, endemic disease, injury prevention (e.g., landmine injuries), and gender- and age-specific vulnerabilities will be lacking.

The goal of any health intervention is to minimize mortality and morbidity. Endemic disease control, especially in a developing country model, is always a priority. All children in developing countries in conflict should receive measles vaccine and vitamin A supplementation to mitigate the complication rate of measles and other infectious diseases, such as diarrheal and respiratory diseases. Malaria, HIV, and sexually transmitted diseases (STDs) also take a severe toll. Once humanitarian assistance reaches these populations, during the acute phase (first 4 to 6 weeks), the mortality and morbidity rates should decline. Priorities in camps shift to maintaining the public health protective infrastructures in water and sanitation, food, and shelter; ensuring security and fuel; and rebuilding the basic public health system. Abuses against women and failures in reproductive health have led to high rates of STDs and pregnancy in refugee camps. WHO Emergency Health Kits, which include safe birthing and surgical supplies to care for a population of 10,000 for approximately three months, can provide immediate assistance in CEs.³⁰

Food Programs

Food programs must ensure proper nutrition for the general displaced population as well as therapeutic or supplemental feedings for the acutely malnourished. These programs also should address micronutrient deficiencies as well as give special attention to the nutrition needs of those with HIV/AIDS or tuberculosis. Emphasis must be placed on maternal and child health, reproductive health, and the protection of those with disabilities and injuries. Attacks on infant feeding centers occurred with regularity in Sudan, Mozambique, Ethiopia, Somalia, Angola, and Liberia, and the diversion of food by warring factions became commonplace.

Protein energy malnutrition (PEM) has three components: malnutrition, micronutrient deficiency diseases (especially those related to a lack of vitamins A, C, B₆, and zinc), and secondary infections. The term *PEM* is often used instead of *kwashiorkor* or *marasmus* to define the state of illness. Indeed, many cases are mixed in their presentation (*marasmus-kwashiorkor*) and difficult to clinically distinguish. Nutritional assessments are performed with population convenience samples, in which new arrivals to the refugee camps are screened, and through cluster sample surveys. The malnutrition rate of children younger than 5 years ranks just below

crude mortality rates as the most specific indicator of a population's health.^{9,18,25,31} The malnutrition rate also determines the urgency for food ration delivery and requirements for supplementary feedings and therapeutic feeding centers. Some interventions are now so routine that they no longer require an assessment before implementation in the acute phase of CEs. Most demonstrable is the provision of vitamin A supplementation and measles vaccine in refugee populations in developing countries. Studies from the early 1990s on CEs have shown that vitamin A reduces mortality and morbidity in malnourished children, especially those with measles (active, susceptible, and exposed) and other respiratory illnesses. Indeed, vitamin A supplementation reduces all-cause mortality in children.³² By the time measles becomes identified in a population-dense camp environment, the mortality and morbidity may already be out of control. Based on this evidence, it has become protocol to provide all children between 1 and 6 years old, at the time of registration into the camp, both measles vaccine and vitamin A supplementation. This being the case, the initial assessment focuses on identifying the population in need of services and in ensuring continuing monitoring through program outcome surveys and surveillance. Relief programs emphasize a primary health care approach, focusing on oral rehydration, feeding centers, immunization, promoting involvement by the refugee community in the provision of health services, and stressing effective coordination of programs and information sharing among the NGOs that deal directly with the recipients of care.³³

Medical Personnel

Medical and nursing assets that are needed most under the developing country model are personnel from public health, preventive medicine and infectious disease, primary care, obstetrics and gynecology, family practice, and emergency medicine.³⁴ For CEs in developed country, the desired expatriate medical and nursing care includes surgery, anesthesia, and emergency medicine.³⁴ Chronic and smoldering countries with CEs require a public health focus; however, it is critical to provide healthcare personnel based on the assessment of need to restore both the curative as well as the preventive public health core of the society. This assessment usually reflects the objectives of individual projects and programs. Typically, assistance agencies use trained personnel from relief, development, and advocacy groups.

UNILATERAL MODEL RESPONSE

In the 2003 war with Iraq, the United States and its coalition partners chose a unilateral approach that did not adhere to Chapter VII of the UN Charter. This approach was based on the assumption that this was first a war that would be short with no major humanitarian crisis occurring. Internal U.S. governmental changes also occurred. Under presidential directive, the Department of Defense (DoD) assumed the lead for humanitarian assistance, a position traditionally played by the U.S.

State Department and USAID's Office of Foreign Disaster Assistance (OFDA). Planning for relief, recovery, and reconstruction was placed under the DoD's newly formed Office of Reconstruction and Humanitarian Assistance (ORHA), later renamed the Coalition Provisional Authority (CPA).

Initially, because it was determined by the DoD that there would be little need for humanitarian assistance, the UN agencies and major NGOs had a minimal role in the planning and received little funding support from the United States. Many, including UNHCR, WHO, and ICRC, had expended their reserve funds in limited preparations.

However, international studies published since the end of the Persian Gulf War suggested that civilian health was substantially worse and that specific humanitarian outcomes might occur. Specifically, since 1990 some indicators demonstrated a progressive decline, whereas others reached a nadir in the mid-1990s before the Oil-for-Food and Oil-for-Medicine programs allowed Iraq to import and distribute food, medication, and health supplies and equipment. Infant mortality rates (deaths in children younger than 12 months per 1000 live births) increased from 47.1 to 108 during the period from 1994 to 1999. During the same time, mortality rates for children younger than 5 years increased from 56 to 131 (per 1000 live births). Acute malnutrition increased from 3.6% in 1991 to 11% in 1996. However, the rate of acute malnutrition decreased to 4% in 2002 because of the coordinated work of Iraqis with UNICEF, WHO, the Red Cross Movement, and several major international NGOs. Increases were seen in reported cases of tuberculosis, cholera, typhoid fever, amoebic dysentery, giardiasis, leishmaniasis, and malaria. It was not known whether this represented a true increase or was the result of better surveillance and record keeping.³⁵⁻³⁹

As a contingency, the main relief resources warehoused by the humanitarian organizations included nationally and regionally prepositioned WHO emergency health, surgical, and safe birthing kits; tents; blankets; water bladders; and high-protein food baskets.³⁰

Many NGOs chose not to work with the military-dominated relief effort. The ICRC was the only humanitarian organization functioning during the war, with specific responsibilities mandated under the Geneva Conventions to mitigate civilian casualties and provide repair to vital infrastructure destroyed during the hostilities. Iraqi national staff previously trained by WHO and UNICEF provided a functional semblance of outbreak control, basic healthcare, and repair of water and sanitation infrastructure.

Unfortunately, widespread looting and trashing of public health facilities and hospitals caused a collapse of the health system. The U.S. and coalition militaries, due to flawed planning, were unprepared and undermanned for the security and recovery needs required under international law as an occupying power. In general, health consequences were similar to those found in the developed country model, where trauma and unattended chronic diseases in the elderly predominate. In time, the United States actively requested and supported the return of UN agencies; however, security continued to be the overriding concern that prevented the rapid return of essential services.

Whether this unilateral approach to conflict and war will represent a new model for dealing with CEs has yet to be determined.

Even with the paucity of NGOs serving in Iraq and Afghanistan, there were more fatal attacks reported among humanitarian aid workers in both countries in 2003 than in any prior year. Of the 76 humanitarian workers killed in 2003, 43 were victims of “terrorist-style or terrorist affiliated attacks.” The majority of victims in both countries were local staff employed by NGOs.⁴⁰

PITFALLS

Problems persist. The world humanitarian community lacks a concerted approach to meeting the needs that occur during CEs. Reforms are needed in the UN and its agencies. NGOs are nonhomogeneous organizations; their proliferation during the past decade has made coordination in the field of operations difficult. Major inconsistencies of Sphere standards occur: the use of basic indicators such as mortality rates in evaluating and monitoring programs are often improperly interpreted or neglected.

Whatever the epidemiological model, the larger humanitarian community has found itself often unprepared and at times overwhelmed with the demands for assistance. Wanton violations of the Geneva Conventions and international humanitarian law make it increasingly difficult for relief workers to maintain security for their programs and projects. The recent trend since the Balkan Wars—to militarize and politicize humanitarian assistance—has made it almost impossible for relief organizations to maintain neutrality and impartiality.

Although both the multilateral and unilateral approaches have desperate flaws that need immediate reform, humanitarian assistance will always require an integrated, international approach with lateral integration, communication, and information sharing of multi-sector and multiagency participants. This cannot be accomplished without coordinating with the leadership of UN agencies and IROs.

The urbanization of populations in warfare has caused humanitarian assistance to move from traditional rural to urban settings. Almost two-thirds of African populations are now living in urban settings with tenuous social and physical protections. Ninety-five percent of the Iraqi population lives in cities where public health infrastructure disrepair and lack of security are major impediments to recovery and reconstruction. Currently, the humanitarian community is unprepared to defend the collapse of urban public health, especially when the environment remains insecure.

Training for work in a CE is essential before deployment. To be both successful and safe, health providers need to expand their knowledge base to include issues of integrated management, transportation, logistics, communications, negotiations and mediation, security, and international humanitarian law. Despite growing trends toward the professionalization of and educating and training the humanitarian community in the late 1990s,

the career requirements for training and education have not kept up with demands.

Children and Disaster

Bruce M. Becker

Children, along with the elderly and pregnant women, are the most vulnerable populations in disasters. Physiologically and psychologically they are less fit than adults are to survive the acute, subacute, and chronic stresses imposed by a disaster. The younger the child, the more vulnerable he or she is. Children depend on their parents or guardians for food, clothing, shelter, hygiene, sanitation, water, medical care, and general personal safety. Regardless of the type of disaster, inevitably a certain percentage of surviving children will be separated from one or both of their parents or guardians, sometimes forever. Without the appropriate stewardship of adults, the hazards imposed on children by the disaster situation are multiplied. Children are more likely than others to suffer from malnutrition in the pre-disaster period and, therefore, are more sensitive to decreased food availability after a disaster when the incidence of protein energy malnutrition and micronutrient deficiencies increases. Children are also more likely to suffer closed head injury during a disaster due to their body proportions. In addition, they are more vulnerable to the risks of dehydration and respiratory insufficiency from acute infection or hypothermia if rendered homeless in the wake of the vast structural destruction that follows many natural and manmade disasters. Disruption of the social fabric of their lives can lead to long-term depression, posttraumatic stress disorder (PTSD), interruption of normal growth and development, and lifelong disability. Sadly, orphaned children are also potential victims of unscrupulous adults who may seek to exploit them in as slave workers, sex workers, or combatants in civil war and rebellion. Children fare as badly or worse than their adult counterparts during and after a disaster because of their unique physical and psychological vulnerability, with age inversely related to increased morbidity and mortality. Disaster planning modules in the past have given children short shrift, with small and inadequate chapters devoted to their needs. Clearly an entire text could be written about the proper medical and psychological care of children in disasters. This chapter will serve as an introduction and overview. References and additional readings are included at the end of the chapter for the interested reader.

Disaster response planners must consider the unique characteristics and needs of children when designing,

preparing, implementing, and assessing any disaster relief intervention. This chapter focuses on and highlights the particular needs of children in disasters. It provides a historical perspective; focuses on current practice; highlights pitfalls; and provides references and additional readings. It is important to note that most medium- to large-scale natural or manmade disasters destroy the homes and social structures of the families of children. The children and their parents or guardians, if they survive, then become displaced populations or refugees. Therefore, it is impossible to discuss the disaster response issues for children without focusing on the medical aspects of children as refugees or displaced populations, as well. This chapter considers both of these issues, which represent a continuum of medical and psychological challenges for children. Acute medical care must be provided in the immediate wake of the disaster (assuming that there is a discrete chronological impact), and then subacute and chronic care must be provided to locally or distantly displaced or refugee populations of children who were forced out of their domestic environment as a result of the disaster itself.

HISTORICAL PERSPECTIVE

In the past, the international community's response to disaster was very disorganized, poorly monitored, and inefficient, focusing on capital investment, structural replacement, and trans-shipment of large amounts of materials such as medical supplies and equipment, clothing, canned food, and tentage. Much of this material was outdated, culturally unacceptable, untranslated, misunderstood, shoddy, and of little use to the affected population, particularly children because almost none of it was pediatric-specific. The cost of transporting, sorting, storing, and distributing these disaster relief materials was quite high, diverting resources that could have been better used in other ways. Moreover, there were unintended negative outcomes resulting from improper use of pharmaceutical agents and equipment by personnel untrained in their use. These historical problems associated with disaster relief were magnified when children were considered. Using the example of

the emergency medical services (EMS) system in the United States, it was only in the very recent past that EMS began to treat children differently than adults in the prehospital setting. This change came about because most of the equipment, medications, and training were completely irrelevant to the care of most children and, therefore, children were not receiving an adequate, medically appropriate, evidence-based approach to prehospital medical care. In the same vein, the disorganized and rarely assessed response to disaster relief that existed before the mid-1980s completely disregarded the separate and even more important medical and psychological needs of children affected by disasters. This was especially tragic because almost half of the population of most developing countries is younger than 15 years, and the most medically devastating natural and manmade disasters typically occur in developing countries. The level of human devastation is a direct result of inadequate intrinsic infrastructure, severely compromised vulnerable populations before the disaster, and inadequate local and nationwide resources to provide acute and long-term responses to the disaster.

Even though many healthcare practitioners were eager to “do something” before there was a change in focus on children affected by disaster, few had experience and almost none was trained specifically in pediatric disaster medicine. Preliminary need assessments were not performed, planning was haphazard, and outcomes research was nonexistent. Reportage ruled. In the 1980s, primary healthcare, which was just beginning to be applied to healthcare development projects in developing countries, began to be applied to refugee and disaster medicine. Concepts of immunization; nutrition; oral rehydration therapy; cooperation and collaboration with the affected populations; involvement of the local ministry of health; collaboration between local and international nongovernment organizations; appropriate information gathering, including postimpact (but prerresponse) assessment; and outcome assessment were becoming more commonplace. This conceptual and process approach to disaster and refugee medical relief has demonstrated increased effectiveness. Despite the increase in the number of articles and texts addressing these concepts and processes, there remains a paucity of information and research in this field, specifically information and research directed toward the treatment of children in disaster, complex emergency, and refugee situations. This is unfortunate because it is quite clear that children make up the highest mortality rates in disaster situations, and those rates are highest for children younger than 5 years.^{1,2}

There are many specific examples of the high mortality rates among children in the disaster literature. In Thailand, Sudan, and Somalia in the 1980s, children younger than 5 years were twice as likely as the rest of the population to die during forced transmigration or in the early days of arrival to a refugee camp, with accrued mortality rates exceeding 105/1000 per month.¹ To provide some perspective, the rate of 90/1000 per month must be compared with a baseline crude mortality rate in the country before disaster of 1–2/1000 per month, an

increase of almost 4500%. Among Ethiopians displaced to Sudan in the mid-1980s, the overall mortality rate was 27/1000 per month, but the mortality rate among children younger than 5 years was 65/1000 per month.³

In the mid-1990s, among Nicaraguan and Honduran children displaced to refugee camps because of the Contra war, babies represented 42% of all deaths and children younger than 5 years represented 54% of all deaths.⁴ During the famine of 1992 in Somalia, the death rate for displaced children was 74%.⁵ During the civil unrest in Rwanda in 1996, displaced Tutsi children represented 54% of all deaths among refugees in camps in Goma, Zaire.⁶ The accrued mortality rate for children younger than 5 years in the Zaire refugee camps averaged 36/1000 per month, 15 to 18 times greater than their baseline mortality rates.

It is clear from these examples that the highest mortality rates among populations who are suffering as a result of natural or manmade disasters and who are also generally displaced or become refugees are children and that the youngest children have the highest mortality rates. These mortality rates reflect tremendous suffering and waste of human capital; they represent the most specific indicators available in the acute and chronic situations of the underlying health status of the population but are likely to be underestimated. The rates are underestimated due to recall bias, the failure to report perinatal deaths in many cultures, and the political forces that inflate denominators (baseline population for increased aid) and deflate numerators (decreased deaths, which represents better health and relief service).

Why are children dying? The common reported causes of death of children caught up in natural and man-made disasters involving civil unrest or war and transmigration to refugee camps include acute respiratory infection, measles, malaria, severe malnutrition, diarrheal disease, injury (gunshots, mines and shrapnel, contusions), and burns.² There is little evidence in the current medical literature that improved response to disaster, complex emergency, and refugee crises has changed either the causes of childhood death or, in many situations, the death rates themselves. Clearly, better approaches to the assessment and treatment of children in disaster situations are needed if great improvements are to be made on these distressing mortality rates.

CURRENT PRACTICE

Appropriate disaster intervention aimed at decreasing the morbidity and mortality of children requires proper predisaster preparation, training, and equipment; prompt and appropriate assessment of the disaster situation; rapid intervention appropriate to the specific disaster and the particular health and psychological needs of the children affected; and short- and long-term intervention strategies. During a disaster, implementation of sustainable programs that address the acute, sub-acute, and chronic predictable problems of children associated with different forms of disaster and complex emergencies is also important.

During the last few decades, disaster medical relief activities have been more scrupulously reviewed, and sufficient data have been gathered and analyzed to allow planners to appropriately train and prepare disaster intervention teams to respond to most types of disaster and complex emergencies that may arise in the world. Some of that data have focused on the needs of children. There are six major pillars that support the foundation of disaster response, particularly as it relates to the care of children: water, sanitation, nutrition, shelter, medical response and treatments, and psychological support. If any of these pillars or supporting columns is inadequately addressed, the protective edifice that the disaster response team or organization is trying to build to help the affected populations will collapse. The following sections briefly address these subject areas from the perspective of children and disaster.

Water

Water is essential for life. Most manmade or natural disasters and complex emergencies interrupt the clean water supply to a population. Earthquakes may destroy wells, urban water lines, and water treatment systems. Hurricanes and tsunamis introduce fecal material, toxic chemicals, and salt water to standing water sources and wells. Combatants in war and civil unrest often destroy water sources as strategic acts of war. The minimum personal water requirement is 10 L per day. It is not acceptable to assume that children require less. Fifteen to twenty liters per person per day is needed for drinking, cooking, and personal hygiene. Twenty to thirty liters per person per day is required for children being fed in collective feeding centers that address the needs of children who are undernourished or malnourished. Hospitals require 40 to 60 L per person per day. Water must be accessible; wells must be within a reasonable distance. Family members must have containers to transport and store water. In most cultures, women, mothers, or older female children are responsible for collecting and managing water. A mother's time spent on water is diverted from other aspects of caring for her children. It is also important to note that contamination of water sources by human contact, especially by the small hands of children reaching through large openings into jars and bottles, is a major concern for the spread of fecal-orally transmitted pathogens such as shigellosis, cholera, and typhoid, which are key sources of mortality for those same children.

Gastroenteritis followed by dehydration may be the leading causes of death in children younger than 5 years in disaster situations. The so-called dirty hands diseases, which include diarrheal dysentery, cholera, typhoid, hepatitis A, polio, and helminthiasis, are prominently prevalent in baseline pediatric populations in developing countries and are transmitted as a result of poor hygiene and a lack of adequate clean water and soap. Providing soap and educating the population about appropriate handwashing before meals and after defecation can have a profound effect on the incidence and new cases of diarrheal disease. Soap distributed to refugees from Mozambique decreased the incidence of diarrhea in chil-

dren by almost 30%.⁷ Water containers with covers or small spouts provided to the same population of refugees led to a 30% reduction in diarrheal disease in children younger than 5 years.⁸

Some members of the disaster response team should have training and experience in the assessment of the water supply and water treatment as well as simple interventions directed at keeping the water supply safe and available to mothers and children. Short-term rapid interventions may involve the provision of a mobile water supply or the installation of temporary filtration systems. Long-term interventions include the drilling of deep or artesian wells that are protected from contamination by fenced wellheads. Soap-and-water carrying devices can decrease the incidence of waterborne and potentially fatal gastrointestinal illness.

Sanitation

The lack of sanitation is a very important problem on-site during and after disasters and complex emergencies. Sewage lines and sewage treatment are disrupted by most natural and manmade disasters. Many countries do not have any toilets, underground sewage, or sewage treatment in rural districts. Children are particularly vulnerable to fecal-oral pathogens. In a Kurdish refugee population in 1991, children younger than 5 years had mortality rates of 15/1000 per month, and more than three quarters of those cases were a result of diarrheal disease associated with malnutrition.⁹

Disaster response teams should be prepared to understand the implications of poor sanitation after a disaster. They should have an ability to assess the sanitation needs of the disaster-struck population and the cultural and sociological parameters of defecation in the affected population. In many developing countries, it is uncommon for children younger than 3 years to wear diapers or other coverings. Defecation takes place randomly throughout populated areas, facilitating the spread of fecal pathogens. It is common for mothers to place children with diarrhea over their legs to defecate, thereby facilitating fecal contamination of the mother and other siblings. Defecation fields, trenches, and pit latrines all provide protection from fecal pathogens; however, responders must consider traditional methods and habits of defecation as well as religious, cultural, and social mores concerning defecation and joint use of facilities across gender and age. These problems are more easily solved in the developed world, where individual toilets are widely accepted but just not functional after disruption by the forces of natural and manmade disasters. Decisions must be made and solutions implemented rapidly because large populations separated from free access to toilets will find other means and sites of relief that are fraught with the potential for spreading epidemics.

Cholera is a common and deadly postdisaster disease. Risk factors include poor sanitation and a lack of soap and clean water. There is a direct relationship between the incidence of cholera in a family and the number of children younger than 5 years in that household.¹⁰ Mortality as a result of cholera is greatest in children

younger than 4 years, with a relative risk of 4.5 when compared with older children and adults.¹¹ Most deaths among these young children occur within 24 hours of diagnosis and hospital admission.

Nutrition

Protein energy malnutrition (PEM) is highly prevalent in children who have suffered a natural or manmade disaster and is a major contributor to death in these children. The case fatality rate (CFR) for most infectious diseases, including measles, malaria, diarrhea, and acute respiratory infection, increases dramatically in children who are also afflicted by PEM. Children who are 0-5 years old are at greatest risk.¹² Even mild to moderate undernutrition can be a significant contributor to the death of children in complex emergencies or disasters.^{13,14} PEM in children after a disaster often is a result of an exacerbation of underlying famine conditions that existed in that population before the disaster. Such postdisaster famine conditions can be predicted based on an understanding of the socioeconomic condition of the population before the event. Pre-existing conditions that will evolve into famine include widespread poverty; intractable death; underemployment; and a high prevalence of malnutrition, with a moderate to large percentage of the pediatric population who were routinely underfed and were experiencing hunger and starvation. Unfortunately, this is not an unusual condition in many developing countries in the world today. The prevalence of PEM is directly proportional to the crude mortality rate in the underlying population of children. PEM in less than 5% of the children's population is associated with a crude mortality rate of less than 0.9 deaths/1000 per month. Conversely, a prevalence of PEM exceeding 40% in the underlying pediatric population generally is reflected in a crude mortality rate of 30-40/1000 per month, an increase of more than 4000%.

A disaster assessment team arriving on-site should be prepared to evaluate the pediatric population's nutritional status. Nutritional assessments of children in these situations focus on changes in the child's weight in relation to his or her height (weight for height [WFH]). Weight and height are easily, quickly, and accurately measured in sample populations of children. Weight is more sensitive than height to sudden changes in food availability. WFH measurements are also appropriate for assessing the effectiveness of feeding programs. Height-for-age (HFA) measurements reflect more chronic nutritional deficiency, and an abnormal HFA is referred to as *stunting*. Both WFH and HFA measurements are compared with established normal values for the particular population being evaluated (a reference population), and the results are reported as Z scores. Z scores are the number of standard deviations (SD) the patient falls above or below the median when compared with the reference population.

In well-nourished populations, less than 3% of children younger than 5 years have WFH Z scores of less than -2, or 2 SD below the median. In countries where children normally experience some degree of undernutrition, up to 5% of those younger than 5 years have WFH Z scores

of less than -2. A nutritional emergency exists if more than 8% of the WFH Z scores among these very young children are less than -2. The prevalence of moderate to severe PEM in a random sample of children younger than 5 years is a strong indicator of this condition in the underlying population. Causes of death of children with severe PEM include dehydration, infection, hypothermia, cardiac failure, and severe anemia. Acute respiratory infection, urinary tract infection, measles, diarrhea (either infectious or malabsorbed), malaria, skin infections, and sepsis are more common and more fatal in children with PEM. Clinical symptoms such as fever and pain may be masked. For example, measles in children with PEM can have a CFR of up to 30% (a <5% CFR is seen in well-fed, healthy children). Infections should always be suspected in children with PEM and treated aggressively.

Thermoregulation is impaired in children with PEM; therefore, extra blankets and co-sleeping with the mother should be encouraged, and these children should not be bathed. PEM also results in limited glucose stores and impaired gluconeogenesis. Hypoglycemia often accompanies infection. Congestive heart failure (CHF) can be seen secondary to fluid overload that may occur in the process of rehydrating children with gastroenteritis and dehydration. CHF may also result from severe anemia with high output failure, electrolyte disturbances, wet beriberi from thiamine deficiency, or cardiac muscle atrophy associated with prolonged protein deprivation. Mild to moderate anemia is very well tolerated in these children; they should not be given transfusions because these will often result in CHF from fluid overload. The diagnosis of dehydration can be complicated because these children are often edematous from hypoproteinaemia. They can be limp, apathetic, or even unconscious. The high prevalence of PEM and the increased incidence of infectious disease explain much of the excess mortality seen in children after disaster, particularly if they become displaced or refugees.

Micronutrient deficiencies, including iron, vitamin A, vitamin C, niacin, and thiamine, are often seen in refugee or displaced children after disasters or complex emergencies. These children may have anemia, scurvy, pellagra, or beriberi. Nutritional deficiencies can persist in chronically displaced children.^{15,16} More than two-thirds of children in a Palestinian refugee camp were found to be anemic.¹⁷

If initial assessment of the underlying population of children affected by the disaster or complex emergency reveals a substantial prevalence of PEM, the relief team should initiate supplemental or therapeutic feeding programs as quickly as possible. Supplemental feeding programs are conducted in the outpatient setting and generally are made available for children whose Z scores are between -2 and -3. Children up to 12 years old may be included, as well as pregnant or lactating women. These programs generally provide an additional 500 calories and 15 g of protein a day in addition to the ordinary rations provided by relief agencies. Supplemental feeding programs either can prepare the food on-site and have the child consume it in a community center or can distribute dry rations to the mother. There are major

social and cultural issues that will impinge on the effectiveness of these approaches. Supplemental feeding programs that distribute wet rations require preparation and distribution at a particular site and intensive administration by the organization. In addition, there is a time cost to mothers who must bring the children there and feed them on-site. Furthermore, children with PEM will be concentrated in one area, increasing the risk for spreading communicable disease. However, a smaller population can be treated with this type of distribution program. Nevertheless, by providing wet feedings on-site, it is clear that the child will receive the supplements. When dry rations are distributed to the mother, the family is responsible for providing clean utensils, having firewood, and doing the cooking. It is likely that some of the rations may be taken from the mother by other family members or sold by the mother to purchase additional items for the family. Cultural constraints often dictate the distribution of food in families, with fathers getting the most, then the male children, who are followed by female children and mothers. This may affect the distribution of supplemental dry rations to malnourished children. Children younger than 5 years with Z scores of less than -3 and/or edema should be enrolled in therapeutic inpatient feeding programs. These children are given 100 calories and 1 to 2 g of protein per kilogram per day in the first week and then 200 calories and 2 to 3 g of protein per kilogram per day until their Z scores are greater than -2.

Shelter

Natural and manmade disasters often destroy homes and lead to widespread homelessness of families. Lack of shelter has a tremendously pejorative effect on children, irrespective of the climate in which the disaster occurs. The disaster medical response team must consider emergency shelter as part of the intervention.

Poorly planned and designed shelters or groups of shelters create one of the most pathogenic environments possible for children and families. Overcrowding and poor hygiene inevitably lead to epidemics of infectious disease. Environmental factors such as exposure, vectors, and lack of privacy exacerbate the psychological distress of children and adults and can lead to subsequent depression and PTSD. It is very difficult to predict the longevity of homelessness among the affected population. For instance, some Palestinians have been in refugee camps since the mid-1940s.

Considerations for preplanning individual and group shelters at disaster sites include security and protection. Many complex emergencies involve some degree of civil unrest, and combatants from both sides are often displaced and share living spaces. This can result in internal turmoil within the encampment. Clearly, this has implications for children; they need to be protected from any incipient violence. Easy access to a reasonable supply of clean water is essential to preserve health in children. Environmental health risks must be considered, including stagnant open water and swamps. In addition, open cooking fires present considerable health hazards to children. Burns from these fires are one of the more com-

mon pediatric injuries treated by medical teams in these situations.

Replacement of infrastructure can be quite important in restoring some social order to the lives of children after disaster. These structures may include playgrounds, schools, and health and nutritional facilities.

Medical Response and Treatments

Upon reaching the impact site, the disaster response team should initiate a rapid health assessment of the children present to determine an appropriate strategic plan for intervention. Team members should determine the major health and nutritional needs of the affected children and create an ongoing health and nutritional surveillance system. They should assess the local response capacity of the underlying population. They also should determine the total number of affected children as well as an age/gender breakdown and average family or household size. This can be accomplished by convenience sampling. It is important to obtain background health information as well, including an understanding of what the main health problems of children in the region were before the disaster; previous sources of healthcare; important health beliefs; the traditions of parents; the social structure of families, including decision-making pathways within the family; and the strength and coverage of public health programs at the impact site, including immunization rates for various childhood illnesses. The assessment team should determine available food supplies and sources and the logistics needed and opportunities to institute feeding programs, if necessary. Environmental conditions need to be assessed, including climate, geography, availability of materials in the field for shelter and fuel, existing shelter and sanitation arrangements, and water. The response team should use existing facilities first whenever possible. Temporary health facilities created by the response team should have a water supply, refrigeration, heat (in a cold climate), windows with screens (in a hot climate), a generator, vaccine and vaccination equipment, including materials to maintain a cold chain and supplies of essential drugs and medical disposables and nondisposables. The medication and equipment should be appropriate for children, including, if possible, items such as Broselow tapes with accompanying medical packs containing sized airway and intravenous equipment as well as standard drugs for resuscitation. Local medical personnel should be included in the relief efforts at the earliest possible stage because of their experience and familiarity with the language, culture, and sociological background of the children, as well as their familiarity with the country and intrinsic health resources. The disaster medical response team should bring in preprinted health records for children. It is likely that health records and vaccination forms will have been destroyed by the disaster and, therefore, will need to be re-created on durable materials that can be maintained long after the team has left the area.

Particular types of disasters and complex emergencies are associated with particular health problems in children. These have been reviewed elsewhere in this text

in the disaster-specific chapters; therefore, they will not be covered in great detail here. However, volcanic eruptions, for example, produce smoke and ash, precipitating acute respiratory illness, asthma exacerbations in patients with chronic asthma whose controller medications have been destroyed, and acute incidents of new asthma and reactive airway disease. Medical response teams should have adequate beta agonists for metered dose inhalers and nebulizer administration as well as steroids and oxygen. Earthquakes are commonly associated with head injuries, orthopedic injuries, and crush syndrome in children; fortunately, crush syndrome has been reported far less commonly in children than in adults. Earthquakes are typically also associated with burns because of electrical fires and disruption of natural gas lines, stoves, and heating units. The team should carry proper burn care supplies and identify a referral destination with burn care capability that is outside of the impact zone. Tsunamis, hurricanes, and floods massively contaminate water supply with fecal pathogens; gastroenteritis and dehydration are very common in children in these settings, as seen with the 2004 tsunami in southeast Asia. The team should have adequate water filtration, purification, and transportation supplies; oral rehydration therapy (ORT); and intravenous equipment in children's sizes, as well as experience in starting pediatric intravenous lines.

Measles has been identified as a leading contributor to mortality in children who are displaced after disaster. Measles vaccination campaigns should be assigned the highest priority by response teams when predisaster vaccination coverage has been poor or is unknown. Vaccination coverage of 80% is considered adequate to induce herd immunity in regular populations but may be inadequate in displaced populations of children, where 100% coverage should be sought. In populations of children where the crude mortality rate exceeds 1/10,000 per day or 3/1000 per month, all children from 6 months to 15 years old should be immunized. Vaccination should be given the highest priority for children with PEM or other underlying medical problems, including infectious disease. PEM, fever, acute respiratory illness, diarrhea, human immunodeficiency virus (HIV), tuberculosis, and acute measles are not contraindications to vaccination. The only contraindication is pregnancy. Vitamin A deficiency increases the CFR of measles; therefore, vitamin A should be administered to all children as part of the nutrition program early on in a disaster response, especially if there has been population displacement. Measles vaccination requires constant refrigeration of the vaccine and appropriate quantities of sterile vaccination disposables.

Diarrheal disease has a high prevalence and high mortality rate in children younger than 5 years in disasters, especially if the water supply has been compromised. Prevention is as important as treatment: establish an adequate supply of clean water situated close to each family unit, distribute soap, and encourage handwashing. The disaster response team should address sanitation as well, providing latrines as quickly as possible at the disaster site. The mainstay of treatment for diarrheal disease in children is ORT. Children younger than 2 years should

be provided with 50 to 100 mL of ORT per stool. Children older than 2 years should be provided with 100 to 200 mL per stool. Feedings should be continued throughout the diarrheal episode. Severe dehydration ($\geq 10\%$), especially resulting from cholera infection, should be treated with intravenous fluids, 70 to 100 mL per kilogram. However, nasogastric tube hydration can be very effective and is more resource-efficient than intravenous therapy; it should only be abandoned if persistent vomiting renders it ineffective. In children with PEM, ORT and intravenous hydration should be carried out carefully to avoid CHF.

If possible, laboratory testing for *Vibrio cholerae*, *Salmonella*, and *Shigella* should be carried out, with appropriate antibiotic response to diagnosis. Children with bloody diarrhea and fever should be treated with antibiotics regardless of the presence of laboratory facilities. Surveillance is very important in managing an outbreak of diarrhea in a population of children after disaster or complex emergency. Surveillance should include case definitions, number and severity of cases, type of diarrhea by pathogen, age-specific and diarrhea-specific mortality, and demographics of the affected population. Cholera epidemics should be identified early on to institute appropriate preventive health measures, including distributing water and soap, reheating leftover food, banning the consumption of fish from contaminated waters, and temporarily separating family members to prevent the spread of infections. Surprisingly, cholera is one of the few infectious agents that can be spread by handling corpses.

Acute respiratory infection may be the leading cause of death in displaced populations of children younger than 5 years. Children with acute respiratory infection who are febrile and younger than 5 should be treated with antibiotics, according to World Health Organization protocol.

If a disaster or complex emergency occurs in a tropical or semitropical environment, malaria becomes a significant risk to children. It contributes to mortality in 25% of children who are infected. Malaria is especially concerning when displaced populations travel from an area of low endemicity to an area of high endemicity because the former lacks appropriate immune response. Patterns of resistance geographically should govern treatment choices. Prevention is very important. Disaster medical relief teams should identify and attempt to decrease the opportunities for mosquito reproduction, particularly in standing water. Permethrin-treated netting, blankets, tents, and clothing are more cost-effective and much cheaper than medical treatments for malaria.

Reproductive health and sexually transmitted diseases are often ignored in disaster response activities. This oversight may be acceptable in the immediate aftermath of a disaster when the saving of lives and rebuilding of essential health infrastructure dominate responders' focus. Nevertheless, in the subacute and chronic phases, with there is disruption of the family unit and social fabric coupled with PTSD and deteriorating socioeconomic conditions, these issues take on a larger significance. Sexual and gender-based violence is common in displaced populations, and this violence is often directed at children because they are more vulnerable. Single moth-

ers trying to feed their children, adolescent girls and boys, and orphaned children of all ages can be ensnared in the sex trade. Universal and free condom distribution and education should be widely available as well as emergency postcoital contraception.

Disaster relief workers should practice universal precautions and should be aware of the prevalence of HIV and AIDS in the indigenous population of the country in which they are working. Medical, dental, and surgical material should be disinfected and sterilized. Use of injections and injectables should be limited. Blood transfusions should be carried out rarely or never, especially if shoddily tested local blood is being used for transfusion as opposed to emergency supplies brought in by the disaster response team. The team must dispose of medical waste and sharp instruments. Many developing countries reuse sharps after minimal or no sterilization procedures, thus promulgating bloodborne pathogens. The disaster response team also should bring postexposure prophylaxis for themselves in case of needle stick or other exposure.

Psychological Support

Disasters and complex emergencies impose a tremendous amount of psychological stress on children. Children who are victims of disaster or complex emergencies are often overwhelmed by anxiety and fear, including fear of death, injury, being separated from their families, or being orphaned. These children may often display regressive or aggressive behavior, depression, and even suicidal behaviors. Many children who were exposed to a 1999 earthquake in Athens demonstrated anxiety or PTSD. There was a direct relationship between the prevalence of these problems and the child's proximity to the epicenter of the earthquake, as well as female gender and their sense of exposure to threat.¹⁸ There is a direct relationship between the parents' response to disaster and the subsequent effects on their children. After an earthquake in Bolu, Turkey, researchers found that the severity of PTSD in children was mainly affected by the presence of PTSD and depression in their father. Fathers who had experienced the disaster and who became more irritable and detached because of these symptoms affected their children more significantly.¹⁹ The prevalence of depression after the Athens earthquake was high, with 78% of children who had experienced the disaster exhibiting severe to moderate PTSD symptoms. Severe to moderate symptoms of PTSD in these children were also associated with high depression scores.¹⁸ A concerning prevalence of depression, PTSD, and anxiety in children was also found in Japan after the Hanshin earthquake.²⁰

Several researchers have reported an increase in the incidence of child abuse after natural disasters. Researchers in the United States studying the effects of the Loma Prieta earthquake in California and hurricane Andrew in Florida concluded that most of the evidence presented indicated that child abuse escalates after major disasters.²¹ Researchers in North Carolina found that the incidence of inflicted traumatic brain injury in children increased most in counties affected

by hurricane Floyd. This increase in incidence returned to baseline levels 6 months after the impact of the disaster.²²

It is clear that both children and parents are affected psychologically by disasters; moreover, the effect on parents can have a domino-like or ricochet effect on their children. The earlier that disaster medical response teams initiate psychological counseling for the child victims of disaster, the more likely they are to circumvent the long-term development of disabling morbidity, including PTSD, anxiety, depression, and suicidal behavior. Restoring "normalizing" social structures, such as schools, playgrounds, and community centers, as well as basic human services—shelter, water, sanitation, food, and clothing—can be as effective as formal counseling in ameliorating the psychologically devastating effects of disaster.

There are also several psychosocial concomitances of disaster and complex emergencies that must be considered when focusing response on children. Disasters in which there are many adult deaths result in widespread orphaning of children. Identification and database services need to be set up soon after the medical response team arrives to try to pair children who are separated from their parents back with their parents or with other appropriate family members or relatives. These orphaned children are especially vulnerable to abuse from adults who may draw them into sexual slavery or forced work situations. In countries with ongoing civil unrest or conflict, children as young as 10 years old who are orphaned or separated from their parents are often drafted into rebel armies and trained to carry out armed warfare. The long-term disturbing psychological effects of these activities can only be presumed.

PITFALLS

1. Appropriate care for children who are victims of disasters and complex emergencies requires proper preparation of the disaster medical response team and an early on-site needs assessment that is specially geared to children before the disaster medical response is launched.
2. Appropriate equipment and training geared specifically toward the treatment of children are a necessity for any disaster medical response team hoping to provide appropriate care for children on-site after a disaster or complex emergency.
3. The basic primary healthcare components normally considered in adult disaster medical relief are equally important in providing relief to children, with the focus on providing water, food, clothing, sanitation, shelter, treatment of injuries and illnesses, and psychological counseling.
4. PEM is a huge problem in children after disasters or complex emergencies because in many countries where these events occur, the children have a prevalence of undernutrition or malnutrition. Rapid nutritional assessment and the provision of therapeutic or supplemental feeding can have a huge effect on decreasing pediatric morbidity and mortality.

5. Effective and rapid immunization programs, especially those focusing on measles, can have a large impact on children in the aftermath of disaster, particularly if the baseline immunization rates in the population were inadequate.
6. Clean water and appropriate sanitation are the two most important interventions in the prevention of epidemics of potentially fatal gastrointestinal infectious diseases in children, who are more prone to fecal-oral transmission of pathogens.
7. Psychosocial issues must be addressed early in a disaster medical response to prevent long-term debilitating PTSD and depression in children.

Psychological Impact of Disaster

Tracy E. Wimbush and Christo C. Courban

The psychological impact of disaster is often immeasurable. Whereas the physical injuries caused by disaster can be visualized, it is much more difficult to identify the psychological trauma that many experience as a result of a disaster event. Though most people who are exposed to even worse traumatic stressors will recover with minimal intervention, all agree that there is no such thing as “no response” when discussing emotional reactions to disaster.

HISTORICAL PERSPECTIVE

Traditionally, disaster medicine has focused solely on the medical and surgical needs of individuals, and little effort was made to meet the emotional and psychological needs of disaster victims and workers. The psychological aspects of traumatizing events such as natural disasters, war, accidents, and terrorism have been a focus in psychiatry for many years, and early reports of psychological trauma after railway accidents occur in the literature as early as 1866.¹ In recent years, those interested in disaster management have given increased attention to the psychological consequences of disaster. As a result, the body of evidence identifying those at risk, documenting signs of emotional trauma, and supporting interventions after disaster has grown significantly.

Although it was not until 1980 that the *Diagnostic and Statistical Manual of Mental Disorders*, edition 3 (*DSM-III*), first codified one of the most devastating psychological outcomes of disaster—posttraumatic stress disorder (PTSD)—many experts believe this disorder existed hundreds of years earlier and suggest that the elements of the disorder can be identified in Homer’s *Iliad*. Others argue that psychological responses to disaster are culture-bound. Supporting this notion is a study by Jones and colleagues,² who reviewed war pension files of 1856 disabled veterans. They found that those disabled from conditions thought to be similar, if not the same, as PTSD, such as shell shock and disordered action of the heart, did not meet the criteria for PTSD. Interestingly, nearly all of the disabled veterans lacked evidence of “flashbacks.” *Flashbacks*, a term used to describe persistent re-expe-

riencing of the event, is a criterion required for the diagnosis of PTSD. Some experts argue that flashbacks are a culturally based phenomenon that became prominent within the latter 20th century when cinema became popular. The suggestion that psychological response to traumatic events such as disaster evolves with culture points to the need for culturally sensitive and up-to-date psychological interventions.

CURRENT PRACTICE

Before determining what interventions are needed after a disaster event, it is important to understand the phases of mental health disturbances after disaster. Researchers describe multiple phases of response. Burkle³ summarizes three main phases. Phase one is the preimpact phase. This phase occurs before the event takes place; the stressor of this phase is worry. Response to this stress ranges but normally includes denial and anxiety. The second phase is the impact phase, in which the disaster is actively occurring. Our knowledge of expected reactions during the impact phase of disaster is credited to the early work of Tyhurst and Glass from the 1950s. They reported that a small percentage of individuals (12%-25%) remain calm and high functioning, whereas an equal percentage demonstrate disorganization, confusion, and other serious coping difficulty. The majority of individuals during the impact phase are found to temporarily have a blunted response, demonstrate a lack of emotion, and evidence bewilderment. During the aftermath phase, also called the recoil or postimpact phase, emotional reactions vary widely and range from relief at personal survival to survivor guilt, feelings of self-consciousness, emotional lability, and numbness.³

Victims of disaster can be classified into three groups. Primary casualties suffer physical injury and acute psychological sequela as a consequence or may experience psychological harm alone. Secondary casualties include affected relatives and friends of primary casualties and witnesses of the event who were not directly affected. Tertiary victims are rescue workers and healthcare providers.^{3,4}

BOX 8-1 COMMON RESPONSES TO DISASTER

Apathy
Anxiety
Denial
Helplessness
Inappropriate joking
Insomnia
Mild confusion
Mood swings
Overinvolvement in survival activities
Restlessness
Terror

Identifying a pathological posttraumatic reaction early is crucial, with many studies showing that early interventions and treatment lead to better outcomes.^{3,4} Triage classifications of disaster rarely screen for or include those at high risk for psychological trauma, thus leading to a substantial delay in detection of this pathologic condition. Many triage algorithms for primary, secondary, and tertiary casualties in disaster exist in the neuropsychiatric literature.⁴ Triage classification should be sensitive and inclusive. Once primary triage identifies the potential need for assistance, mental health teams can further triage and determine the need for and timeliness of treatment.

There is a spectrum of psychopathology associated with trauma. Victim responses vary, and one victim may manifest a wide range of illness. Most victims manifest only mild symptoms that often resolve without intervention. A list of common symptoms is found in Box 8-1.¹ Providers should be cautioned against classifying severe reactions as a “natural” response to a disaster event because this may prevent early intervention.³ A list of commonly associated psychopathological features related to trauma is provided in Box 8-2. PTSD is by far the most notable psychological consequence of trauma (Box 8-3). However, providers are cautioned not to ignore other potentially treatable pathological features, such as major depression or anxiety disorders, in efforts to diagnose PTSD.⁵

PTSD is diagnosed in persons exposed to an extreme stressor or traumatic event who manifest the following three groups of symptoms:

1. Re-experiencing of the event, or “flashbacks”
2. Avoidance of any stimuli that reminds the victim of the event and a decreased ability to feel emotion (also known as “numbing”)
3. Hyperarousal, which is characterized by increased startle response, anxiety, and irritability

BOX 8-2 PSYCHOPATHOLOGY ASSOCIATED WITH TRAUMATIC EVENTS

Depressi

BOX 8-3 DIAGNOSTIC CRITERIA FOR PTSD

Exposure to a traumatic event
Event is persistently re-experienced (flashbacks)
Avoidance of stimuli associated with the trauma and numbing of general responsiveness
Demonstration of increased arousal
Symptoms last at least 1 month and cause significant impairment or stress

Symptoms must be present for a least 1 month at the time of diagnosis.^{6,7} PTSD is the fourth most common psychiatric disorder in the United States.⁸ Several risk factors for the development of severe PTSD have been identified. They include serious physical injury, persistent anger, witnessing the death or injury of others, dissociation, poor social support, and intense exposure to the traumatic event.⁹ PTSD may be acute or chronic. If symptoms persist for more than 3 months, chronic PTSD is diagnosed.^{6,7}

Davidson⁹ divides prevention of PTSD into three methods: primary (preventing exposure), secondary (preventing the development of symptoms immediately after traumatic exposure), and tertiary (preventing the worsening of PTSD). Although preventing exposure to trauma is ideal, circumstance rarely allows this. Efforts aimed at secondary treatments suggest that targeting central nervous system disturbances with medications, such as hydrocortisone and propranolol, within weeks of the event may prevent the development of PTSD symptoms.⁹ Tertiary treatments often consist of counseling and prescribing medications. Initial counseling can often be done by nonspecialists and should emphasize education and convey feelings of safety and support. When greater assistance is needed, research suggests that exposure therapy, cognitive therapy, and interpersonal therapies may be effective.⁸ Effective medications include selective serotonin-reuptake inhibitors (SSRIs), tricyclic antidepressants (TCAs), and monoamine oxidase inhibitors (MAOIs) and anticonvulsants.^{6,8} A list of effective medications and their target symptoms is provided in Box 8-4. It should be

BOX 8-4 MEDICATIONS USED FOR TREATMENT OF PTSD

SSRIs (shown to be effective on all three symptom clusters)

Sertraline (Zoloft)
Paroxetine (Paxil)

MAOIs (shown to be effective in all three symptoms but used with caution due to potential for adverse interaction with alcohol)

Phenelzine
Brofaromine

TCAs (especially helpful with intrusive symptoms)

Amitriptyline
Imipramine

Anticonvulsants

Lamotrigine

Benzodiazepines are rarely indicated and should be used with caution.

noted that many experts caution against the use of benzodiazepines in patients with PTSD.^{6,8}

Another secondary PTSD prevention method includes critical incident stress management (CISM). The most commonly used element of CISM is critical incident stress debriefing (CISD). CISD, developed by Mitchell in 1988, is commonly used as an intervention after an unusually traumatizing event. It is primarily aimed at rescue workers and other tertiary victims, including nurses, physicians, and even 911 dispatchers but has recently been widely applied to groups ranging from financial workers after bank robberies to prisoners after the murder of a fellow inmate.^{10,11} Even though there are many variations of CISD, a debriefing is generally a group session facilitated by a mental health professional and a group member who was not part of the traumatizing event. During the session, participants recount their experiences and express fears and concerns while facilitators acknowledge victim experiences and discuss coping strategies. The goal of CISD is to normalize the crisis experience, prevent the development of poor coping mechanisms, and assess the need for follow-up.^{6,12,13}

Pioneers of CISM, Everly and Mitchell, point out that CISM, or variations of it, have gained great popularity and are becoming a “standard of care” in many industries.¹⁹ Examples of industries that use their crisis management technique include the U.S. Air Force; the Bureau of Alcohol, Tobacco, and Firearms; the Australian Army; and the Massachusetts Department of Mental Health.

Although CISM, specifically CISD, is generally accepted, opinions differ regarding its effectiveness.¹²⁻¹⁶ Wessely and Deahl¹⁴ comment: “The effectiveness of psychological debriefing and other early interventions remains one of the most contentious areas of mental health research.” Research findings often contradict each other, and many point out the lack of randomized controlled studies in the literature.^{14,17} In a meta-analysis of single-session debriefing after psychological trauma, Van Emmerik and colleagues¹⁸ found that CISD did not improve natural recovery after psychological trauma. Weiss and colleagues⁵ conducted a survey of 46 acknowledged international experts on mental health and disaster management and found that psychological debriefing immediately after disaster, while valued by some, was mostly viewed as useless and even potentially harmful. Others point out that the positive effects of CISD are more probable and that harmful effects are reduced when the facilitators avoid common mistakes, such as failure to have an adequate number of and properly trained mental health providers, allowing breaks in confidentiality, allowing CISD to turn into psychotherapy sessions, lack of a CISD strategy team, and a general lack of understanding of the CISM process.^{6,12}

Realizing the confusion surrounding the use of CISD and CISM in general, Everly and Mitchell recently clarified terminology and provided updated information on the use of CISM.¹⁹ They explain that CISD refers to one debriefing session of CISM. The session generally lasts 1.5 to 3 hours and is recommended 2 to 14 days after a critical incident. They caution that in cases of mass disaster, CISD is not recommended until 3 weeks after the event. Even though CISD is often used alone, Mitchell

contends that it was never intended to be a stand-alone intervention or a replacement for psychotherapy. Rather, CISD is intended to be a single component in the CISM system. There are eight core components of the CISM system. These components are listed in Box 8-5, and each is briefly described in the remainder of this section.

The first component of CISM is precrisis intervention. The goal of this component is to identify those at risk of psychological trauma/crisis and to provide information to them. It also consists of stress management education, stress resistance training, and crisis mitigation for team members and management.

The second component of CISM consists of crisis intervention programs. Examples include demobilization, staff consultation, and crisis management briefings (CMBs). The goal of these sessions is to allow for psychological decompression and provide opportunity for stress management. Decompressions are intended for emergency medical services personnel and should occur immediately after a shift when there has been exposure to a critical event. Staff consultation is intended to provide advice for command staff. Examples of staff advisement recipients include disaster response team leaders, nursing supervisors, and fire captains. CMBs are similar to decompressions but are intended for use with civilians. Examples of groups needing a CMB might include teachers after a particularly violent school event or store workers after a robbery.

The third component of CISM is defusing. The goal of defusing is to allow for symptom mitigation and to give opportunity for closure. It also serves as an opportunity to triage those needing greater assistance. Defusing is a small-group discussion held within 12 hours of the critical incident in which group members are encouraged to discuss events that have just occurred. Defusing has three phases: (1) introduction of the debriefing team, (2) exploration of the experience, and (3) providing information about expected emotions and availability of resources.

The fourth component of CISM is the aforementioned CISD. As intended by Mitchell, it is a seven-phase small-group discussion:

1. Phase one is *introduction* of the team.
2. Phase two is a *fact phase*, in which members describe their role in the event.
3. Phase three is the *thought phase*, when participants explore their thoughts that occurred during the event.

BOX 8-5 CORE COMPONENTS OF CISM

Preincident preparation

Crisis intervention programs
Demobilization, staff consultations, and/or crisis management briefings

Defusing

CISD
Individual crisis intervention
Pastoral crisis intervention
Family CISM and/or organizational consultation
Follow-up/referral

4. Phase four, the *reaction phase*, allows individuals to express their emotional reactions or feelings.
5. The *symptoms phase*, in which participants explore the physical, emotional, and behavior symptoms since the event, is the fifth phase.
6. The sixth phase is a *teaching phase*. During this phase the debriefing team helps to normalize participants' feelings and provides information about expected reactions.
7. The seventh phase is the *re-entry phase*, in which the meeting is summarized and questions are answered.

CISD typically takes two hours and should occur 1 to 14 days after the crisis. However, it should be delayed further in the setting of mass disasters. As with defusing sessions, its goal is also to allow for symptom mitigation, closure, and triage. Again, in its original form, it is not intended as a stand-alone intervention.

Other components of CISM, such as individual crisis intervention, pastoral crisis intervention, and family/organizational CISM, should be available on an as-needed basis. Follow-up/referral is key, and the CISM leader must make an effort to maintain relationships with their community providers to make the referral and follow-up processes function seamlessly.¹⁹

PITFALLS

Although clear benefits of CISM are still debatable according to the research, there are definite pitfalls to avoid when dealing with the psychological impact of disasters:

- Failure to recognize that everyone has some type of emotional response to disaster and providing support only to those exhibiting the most obvious or dysfunctional responses
- Evaluation and treatment of medical and surgical injuries without acknowledging the psychological ramifications of a disaster event
- Failing to recognize early warning signs of poor emotional coping; CISM is often an afterthought to the initial response
- Using CISD as a stand-alone intervention rather than as a single element of the CISM plan
- Having poorly trained or untrained individuals lead CISM efforts

Ethical Issues in the Provision of Emergency Medical Care in Multiple Casualty Incidents and Disasters

Pinchas Halpern and Gregory L. Larkin

Disasters and multiple casualty incidents (MCIs) affect every corner of the globe. Although natural disasters and wars have plagued humanity for thousands of years, man-made MCIs comprise a relatively new and growing threat with which medicine must contend—even in peacetime. Citizens of all nations have increasingly encountered MCIs that, without warning, can instantly overwhelm the capacity of both prehospital and hospital-based systems, imposing significant clinical, organizational, and even ethical challenges. Disasters and MCIs introduce unique moral, triage, resource allocation, and public health issues. The disaster paradigm demands rapid reorganization of medical systems and, in tandem, a recalibration of familiar ethical and moral codes that govern providers during times of stability. Many of the most crucial moral dilemmas can be anticipated, however, and policies can be developed in advance that clearly delineate the duties and priorities for medical support personnel during MCIs and disasters. Prospective ethical deliberation, advance austerity planning, and prophylaxis policy can streamline moral medical decision-making and ensure optimal service delivery downstream to both individual patients and the public at large.

The chronology of preparedness for MCIs and disasters involves three stages: (1) pre-event, (2) event, and (3) postevent. Each stage may be addressed by different medical caregivers, and each poses somewhat different management, clinical, and ethical dilemmas. Major dilemmas within the context of these three timed stages include adequate preparation for eventualities, scene triage and transport, duty to treat, scope of practice off site, stewardship of resources, and ethical long-term goals of fairness in matters of rehabilitation. This chapter will focus mainly on overarching ethical challenges and event-based dilemmas that face emergency medical services (EMS) and emergency medicine (EM) providers in the throes of MCIs and disasters.

HISTORICAL PERSPECTIVE

Over the years, sets of ethical rules have been developed to guide medical personnel in their work, but they usually do not address MCIs and disasters, thereby creating potential uncertainty. Many of the accepted practices have little scientific basis and therefore compel physicians to use common sense. However, common sense may sometimes contradict generally accepted ethical guidelines or leave physicians no choice but to apply some intuitively created adaptation of the ordinary ethical rules to a situation that was not considered when the rules were originally formulated.

In the following are some examples of sets of ethical rules composed throughout history, according to which medical personnel are expected to practice. The Hippocratic oath¹ has been taken by newly appointed physicians in the West for centuries. Inspired by the Pythagoreans, this classic treatise dictates that the physician must be ready and willing to assist a patient with any medical problem under any circumstances, without any economic or other stipulation: “The regimen I adopt shall be for the benefit of the patient according to my ability and judgment and not for their hurt or for any wrong. . . . Whatsoever house I enter, there will I go for the benefit of the sick refraining from all wrongdoing or corruption.”

The Geneva Conventions² are also concerned with the obligation of integrity and respect of the physician toward the practice of medicine. They regard the patient’s health as being the first priority for the physician, who is mandated to use the power of medicine for the general good and maintain good relationships with his or her colleagues, while forbidding any kind of discrimination among patients.

Basic Principles

Borrowing from Beauchamp and Childress's concepts of ethical principlism, Priel and Dolev³ define four principles on which routine medical ethics are based:

1. **Beneficence:** This important Judeo-Christian concept enjoins medical staff members to do their best to optimize outcomes and prolong the life of the patient/victim.
2. **Nonmaleficence:** This is the classic notion of *primum non nocere*, or "the first thing (is) to do no harm." This is the ordering principle of most emergency medical ethics.
3. **Respect for autonomy:** The medical staff must engage in full disclosure with patients and honor their own informed decisions regarding their own medical care.
4. **Justice:** The resources and means of medical personnel must be equitably distributed among all victims.

These four principles are not absolute, and shifting circumstances may dictate their reordering or prioritization. They may even contradict each other. For example, a surgeon's desire to do good for a patient through an operative procedure may also cause the patient some short-term discomfort or even harm from complications. Therefore, providing both beneficent and nonmaleficent care can create a conflict of principles, whereupon the clinician must choose one principle over another.

Medical Organizations

Many medical organizations have developed ethical codes, but few have specifically addressed the issue of MCIs and disasters. The World Medical Association (WMA) code of ethics has a specific section on disaster care.⁴ The code of ethics of the American College of Emergency Physicians (ACEP) specifically addresses situations in which "the resources of a health care facility are overwhelmed by epidemic illness, mass casualty, or the victims of a natural or manmade disaster" and states that it is the duty of the emergency physician to "focus health care resources on those patients most likely to benefit and who have a reasonable probability of survival."⁵ The American Academy of Emergency Medicine's code of ethics does not address disaster/MCI situations.⁶ The ethics code of the American College of Physicians does not contain specific mention of the care of victims of disasters or MCIs,⁷ whereas that of the American Medical Association (AMA) states in its ethics code as follows: "... physicians and other health professionals should be knowledgeable of ethical and legal issues and disaster response. These include: (a) their professional responsibility to treat victims (including those with potentially contagious conditions); (b) their rights and responsibilities to protect themselves from harm; (c) issues surrounding their responsibilities and rights as volunteers, and (d) associated liability issues."⁸ Since studies have demonstrated the poor state of preparedness of medical professionals for disasters and MCIs, such as in the event of bioterrorism,⁹ the AMA code also states that "... a social obligation for physician response can be defined,

then certainly a derivative obligation can be placed on the profession—an obligation to insure that its members are prepared . . . to effectively respond. This obligation of the profession must be not only clearly defined but expeditiously met."

The European Society of Emergency Medicine (EuSEM) has no explicit code of ethics. The World Association for Disaster and Emergency Medicine's Health Disaster Management (WADEM) states¹⁰:

Triage . . . means that scarce resources will be used to provide the maximum benefit to the population at large, even if it means that single victims who might have been saved under other circumstances are sacrificed for the greater good. However, when the triage concept is expanded into other management areas, the concept becomes more difficult to accept. For example, should limited water resources be distributed in a manner so as to provide the minimum amounts needed to sustain life to only a part of the population, and accept the high probability that the rest will die of thirst? Or should 1 litre (less than the critical threshold) be distributed to everybody, well aware that then everybody will succumb, but at a later stage in the disaster? Since ethics, as such, are not natural laws, but human 'inventions', how is what decided deemed to be ethically correct?

The ethical principles of the Israeli Medical Association (IMA) state: "In an emergency, the physician may act according to his best judgment, thus effectively absolving the physician of requirements such as informed consent, privacy, the patient's right to choose a caregiver and provision of information."¹¹ U.S. common law does not impose any duty to render aid or assistance to a person in need, even if one could do so with no risk to oneself. However, experts point out that health providers could be required to provide care in the event of an emergency through licensure requirements.¹² In addition, even though individual physicians do not have a duty to provide care, hospitals and other institutions sometimes do, particularly for emergent situations. The current legal establishment, including the requirements of the Americans with Disabilities Act, seeks to expose physicians while still encouraging them to act. The system provides weak incentives to be a hero. So far, only the Model State Emergency Health Powers Act (MSEHPA) has systematically addressed the duty to care issue.¹³ Even though the MSEHPA is not law, it does serve to offer guidance to state legislators and may influence what types of laws and schemes will be enacted. For example, MSEHPA would allow states to *require* healthcare providers to provide care in the event of emergencies. The duty does vary with risk, since a scheme that would overburden healthcare providers would be unacceptable.¹² Israeli common law (1988) states that "it is the duty of a person to assist another person. . . in immediate severe danger to his life. . . when he can do so without endangering himself or other."

The International Red Cross and Red Crescent Movement's code of conduct in disaster relief states: "Aid is given regardless of the race, creed or nationality of the recipients and without adverse distinction of any kind. . . . Aid priorities are calculated on the basis of need alone. . . . We hold ourselves accountable to both those we seek to assist and those from whom we accept resources."¹⁴ The ethics code of Magen David Adom

(MDA), the Israeli national EMS organization, includes the following text regarding disaster and MCI: “. . . to treat victims by priorities set according to medical criteria, without any other considerations such as age, sex, religion, nationality, social or economic status. . . caregivers will, as a rule, attempt to save the largest number of victims possible, even at the possible detriment of the chances of saving an individual victim. . . to treat victims while guarding the victims’ and the caregivers’ safety as well as possible. Determining the correct balance between risk to victim and risk to caregiver is the responsibility of the caregiver and the event commander’s.” (Personal communication, Pinchas Halpern, MD.) The ethical code of the Israeli Army Medical Corps assumes that the operational protocols governing the administration of medical care in the field cover potential ethical dilemmas and does not deal with the issue specifically.

MCI AND ETHICAL ISSUES ARISING FROM IT

All the ethical codes presented here demonstrate a continuity of principles involving patient-caregiver relationships as well as physician-system relationships. Thus, according to these more classic codes, the physician must be professionally and logistically prepared to manage disasters and do what is best for the patient, including doing everything in his or her power to save the patient’s life. The physician should not discriminate among patients but treat them with a uniform, balanced, and just approach. The physician ought to share his or her decision-making with patients and provide them with truthful information about treatment and prognosis, except when sharing information is expected to cause any delay in or otherwise negatively affect patient care. How an MCI changes the order of these principles and relative contribution of each level of obligation is discussed next.

MCI is defined as a state in which there is an imbalance between the numbers or types of injured who need medical care and the medical ability of the emergency systems to deliver *optimal* care to each individual. Disasters may be defined as MCIs that involve significant disruption of the infrastructure (human, logistic, or medical) of the region/nation coping with the event (e.g., natural disaster, war). The effects of disasters, such as famine and epidemics, may be prolonged and result in an extended need for medical care, with a more complex interaction between purely medical and logistic support (e.g., water and food supplies, shelter). In an MCI or a disaster, some of the ethical principles previously mentioned may not be realistically applicable and therefore raise some interesting ethical issues:

- *Beneficence*: If the physician were to act according to this principle of maximizing the good, he or she would be expected to spend an inordinate amount of time on only one or a few patients and would essentially fail to fulfill his or her ethical obligations toward the rest of the patients who require care. Should the caregiver then focus treatment on one person, or partially take

care of a maximum number of patients, or perhaps only take care of patients for whom it is cost-effective to intervene, thereby only partly fulfilling the beneficence principle?

- *Distinction without discrimination (nondiscrimination)*: It is generally agreed on that patients must not be discriminated against with regard to receiving medical care and the allocation of resources. This issue takes on greater significance during an MCI since it is, by definition, a situation in which there are not enough resources relative to patient requirements. Discrimination among patients must occur, but on what basis should this be done and in a way that does not introduce any form of unfair or improper discrimination? Should medical treatment be administered according to the criterion of severity of injury or according to the patient’s age/social status/benefit to society, ethnic group, etc.? Decision rules that optimize outcomes for all concerned in disasters have not been validated. If the decision was made to deliver medical assistance according to the criterion of injury severity, would it be appropriate to favor patients who are injured severely and whose lives can most likely be saved if they receive immediate care, or would it be better to favor potentially fatally injured patients whose odds of survival are low but who may have a remote chance at survival? This question of treatment priorities is one of the most difficult ethical issues during an MCI.
- *Nonmaleficence*: Due to the nature of an MCI, caregivers may be forced into making critical decisions regarding treatment and evacuation of individual casualties based on superficial evaluation and without the guidance of diagnostic techniques that are normally available in modern medical practice. In addition, caregivers may be under special duress due to personal risk or discomfort. As a result, errors may occur in the diagnosis (e.g., undertriage or overtriage), which may harm certain patients. Should providers in MCIs be liable for these harms, and does the liability of a volunteer differ from that of a nonvolunteer?
- *Patient autonomy and right to information*: During an MCI, this principle may need to be subjugated due to the overarching need for expediency in administering care because medical personnel may not have enough time to share decisions regarding treatment with the patient. Professional and policy considerations regarding the type of injury or available hospital facilities will dictate where the patient will be evacuated, even against a patient’s wishes or best interest from other perspectives (e.g., closeness to home). When a person refuses to receive medical care, the medical personnel will have no time to decide whether the person is rational, thus raising the question whether coercion or force should ever be used to administer medical care during an MCI. Also, how and to what extent should the patient’s requests to choose a hospital or to be evacuated with relatives be considered? Should more time be devoted to every patient to explain to him or her the medical care that will be given? Should the explanations be foregone to care for more patients faster and more efficiently?

- *Staff safety*: There are situations in which the cause of danger has not yet been neutralized (e.g., rescue of wounded persons from a collapsing building; terrorist activity in which there might be an additional explosive charge; care of a chemically, radiologically, or biologically contaminated patient). How should medical personnel behave in such cases? Should they administer care while risking their personal safety, or should they wait until the cause of danger is eliminated? How much personal risk is acceptable? Should medical personnel be compelled to receive vaccination for potential bioterrorism weapons (e.g., smallpox) before or even after an event has occurred? Should nonvaccinated personnel be forced to treat contagious patients even though these physicians had previously refused (or were unable) to receive the vaccine? Which medical personnel should receive limited prophylactic antibiotics in case of an attack with anthrax? Should physicians be forced to respond to a call to manage a chemical incident even though their hospital may not be completely prepared for the event and personal protection equipment may be suboptimal or lacking?
- *Use of nonstandard or investigational procedures and drugs*: Advancement of medical knowledge is based on experimentation. For example, many new MCI triage methodologies have been proposed by public and private sources. How should they be tested? Should physicians accept grants or other inducements to study an unproven technology in a personal experience with an MCI? Experimenting in a disaster/MCI situation produces specific ethical issues not usually addressed during Institutional Review Board processes, and there are few contemporary guidelines.

The unique reality during an MCI creates difficult ethical issues arising from the fact that life is often threatened at an alarming rate; in the heat of a novel disaster, old platitudes and even widely accepted medical ethical codes may no longer apply in their original form.

CURRENT PRACTICE

Real-Time Ethics During MCIs and Disasters

Triage

Some authors agree with the ethics of utility and would counsel medical personnel to reduce morbidity and mortality as much as possible during an MCI.¹⁵ The concept of utility attempts to maximize the general good and may seem to be at variance with the traditionally accepted principle of doing the utmost for the individual patient, even when ignoring some patients may raise the level of the cumulative benefit. During an MCI, providers must be prudent stewards of the limited resources entrusted to them. It would, therefore, be wrong for a clinician to devote his or her energies to

only one patient since, by doing so, the odds of survival for other casualties may be unfairly limited. In an MCI, equitable sharing of resources based on need may eclipse the first-come, first-served practice of routine operations in peacetime.

Assuming that a utilitarian sharing of resources is an appropriate paradigm shift for an MCI, there is still a need to set treatment priorities. Fortunately, there is broad agreement on which victims a clinician should approach first. Those with a lethal injury or in a perimorbid status will be managed expectantly, whereas those with serious but nonlethal injuries are often given high priority. The literature offers a number of suggestions to determine the order of treatment, but studies have documented the high rate of overtriage and undertriage in MCI situations.^{16,17} Before we accept this evolution in attitude, it behooves us to consider other potential ways of setting treatment priorities in an MCI:

1. *Randomly choosing the order of patients to treat*: This position is based on the concept that every person has an equal right to receive medical treatment and, as such, it affords every casualty an equal chance to be chosen via random selection. The problem is that it does not allow every person an equal right to survive: caregivers may invest their time in treating individuals whose lives are not at risk while the other untreated patients may die. This approach is not consistent with the principle of reducing the mortality in as many cases as possible or with the principle of fair and just distribution, which correlates the extent to which a person needs treatment with the extent to which he or she is actually treated.
2. *Choosing according to "first-come, first-served"*: This model may appear fair and, like the previous method, may connote a certain randomness. It may, however, portend greater casualties over time, and it is also inconsistent with the principle of equitable distribution of resources based on need. Also, rules set according to the sequence when casualties arrive on site—thereby determining who will be "first"—seem unacceptably arbitrary.
3. *No treatment to anybody*: Team members are not capable of making a decision of whom to treat first; therefore, they prefer not to administer any treatment until sufficient personnel reach the scene so that all patients can be treated equally. This theoretical solution contradicts the principles of beneficence and nonmaleficence. Withholding time-sensitive benefits and causing harm are both antithetical to the clinician's ethical duty.
4. *Using nonmedical standards (e.g., gender, age, profession, social status, contribution to society, ethnic origin)*: In times of national crises or war, saving a president or a general may have collateral benefits for the good of the nation-state, and it seems natural to first help a wounded child or an esteemed public personality. However, given that all people have equal rights to live regardless of status, age, gender, origin, creed, or disability, physicians must not discriminate against patients who have legitimate needs for care. Ideological issues must not eclipse the humanistic priorities embodied in ethical rules.^{18,19}

5. *Urgency of need*: The priority of treatment is determined according to the severity of the injury and the likelihood of benefit from care. The World Medical Federation has suggested the following scale of priorities:

- *First priority*: victims whose lives are at risk and can be saved by an urgent medical treatment
- *Second priority*: victims whose lives are not at immediate risk but who need immediate medical treatment
- *Third priority*: victims whose treatment may be delayed for an extended period
- *Fourth priority*: victims who suffer from emotional reaction to the event
- *Fifth priority*: victims who are too severely injured to be rescued

Such a scale of priorities may be considered immoral at first glance, like “abandoning a victim in the field.”¹⁵ However, herein is the major difference between an MCI and a routine event. The exigency of an MCI dictates the rule of reduction of morbidity and mortality as well as significant suffering in as many cases as possible. Adhering to this rule means preferring several severely injured victims who might be rescued over a near-fatally injured person who has only a slim chance of survival. Healthcare does not have to be equally distributed; it has to be *equitably* distributed, with each victim receiving care according to medical need. This system determines treatment priorities at the scene, but it is also valid in determining the priority of evacuation to hospitals.

Based on these two principles—reduction of mortality and permanent morbidity in as many cases as possible and giving priority of treatment according to the severity of injury—a working scheme has been in place for years in all EMS/EM protocols for MCI triage. Triage is from the French word *trier*, “to sort,” and sorting patients according to need is critical to “determining the order of priorities to medical treatment, based upon prognostic observations and evaluation.”^{15,17} Triage is performed at the scene in parallel (observing the entire scene simultaneously) and in tandem at the medical facility (triaging patients as they arrive). In practice, scene triage implies that before medical treatment begins, medical personnel will scan the scene and sort the victims into various categories according to the severity of their injury. Medical personnel begin treatment and evacuation only after the evaluation of all the wounded and consideration of extant resources have been completed. This brief planning stage is not “wasted” since it allows the medical personnel to evaluate the situation and determine who needs them most. The evacuation of victims from an MCI scene will take place according to the principle of the severity of injury. First to be evacuated will be unstable victims—those who suffer from a severe breathing disorder, an uncompensated situation of trauma, or a deteriorating state of consciousness. Following will be the stable but urgent victims, and lastly will come nonurgent cases. Often, the priority of evacuation is not identical to the priority of treatment (e.g., a patient with a pneumothorax needs extremely urgent treatment; however, once

treated on-scene, he or she is no longer defined as requiring urgent evacuation).²⁰ Both treatment and triage during an MCI must be orchestrated by well-trained and experienced disaster medical personnel. Minimizing the number of undertriage and overtriage situations will maximize goods and minimize harms. Triage must take into account patients who arrive at hospitals, patients already there, patients expected to arrive, and the resources available to them all on a dynamic, minute-by-minute basis.

Patient Autonomy

A recent medical newsletter opined: “In a massive epidemic, such *niceties* as patient autonomy, detailed record keeping, personalized care . . .” will be sacrificed.²¹ Indeed, the principle of respect for patient autonomy may be overruled in certain disaster situations if it contradicts the main objective of providing the most good to the greatest number of victims.²² This is not to say, of course, that respecting patient autonomy is not terribly important; rather, all attempts should be made to listen to the patient’s specific medical wishes when possible, even though there will be little time. Specific wishes may be respected when they do not contradict the benefit of the majority of casualties and/or the operational requirements and protocols in force during the event. An exception to this rule may be the attempt to evacuate small children together with a parent or relative.

Personal Security of Medical Personnel During an MCI

Medical personnel work in cooperation with additional emergency authorities, such as the police and security forces. Scene safety includes not only the site of the event, but also the care sites. Thus, hospitals may be damaged and rendered unsafe by natural disasters. Hospitals have come under attack in battle zones, and water and food contamination endangers medical personnel as well as the populace. Terrorists have targeted hospitals, and chemical and biological agents pose grave risks to medical personnel both on-site and in care facilities. Balancing personnel safety and casualty needs is usually an ad-hoc decision to be made on-site by the medical commander in consultation with security and other rescue force commanders. Principles, however, must be set a priori. The principle of utility (i.e., maintaining the safety and thus functionality of medical forces who are usually not trained rescuers or fighters) must be balanced with the duty of the medical personnel to offer time-sensitive care as soon as practical. Noteworthy, the Israeli National EMS, MDA, forbids its thousands of underage volunteers to enter the scene of a disaster, but many have still participated in MCI care by functioning on the periphery of the site in areas declared safe by scene commanders. In this way, medical service is given to the victims while minimizing risk to the medical personnel. Having said that, 12 EMS personnel were injured and two killed in the line of duty in MCIs in Israel between September 2000 and September 2003.

Bioterrorism and Epidemics

Despite the 2002 anthrax attacks in the United States and the SARS mini-epidemic of 2003, no modern nation has had to deal with large-scale epidemics with modern means. Even though there is lack of experience and evidence-based information, it is important to at least mention the ethical issues likely to arise from such a situation, which presumably would have a potentially huge impact on a society and its medical system. An abbreviated listing includes:

1. The intrinsic dialectics between the good of society and that of the individual, as evidenced by the questions of whether to limit an individual's movement or his or her autonomy to decide whether to receive a vaccine or care versus society's need to isolate the contagious sick and to treat a contagious individual, perhaps by force
2. The application of experimental treatments during the epidemic, in lieu of existing therapy (pure research) or when other viable therapies are lacking
3. The responsibility of society toward those suffering side-effects of coercive (or even voluntary) therapies, medical personnel family members who contract a disease, affected caregivers, etc.
4. Forcing physicians to receive prophylactic antibiotics or vaccines
5. The right of physicians to refuse to care for contagious patients if these physicians refused (or were unable to or were not offered) vaccines/prophylactic treatment
6. Forcing physicians to remain in the hospital for extended periods to minimize disease transmission
7. Allocating scarce resources to the public versus medical/rescue personnel or politicians/defense forces, etc.
8. Forcing patients to seek care at community clinics by denying access to hospitals
9. Disseminating classified research information to the civilian sector
10. Withholding or modifying information to preserve public order and compliance
11. Manufacturing scarce medications in infringement of patent rights
12. Forcing private companies to produce needed medications
13. Forcing hospitals to take in contagious patients even though it will likely affect their income by turning away other patients
14. Permitting the government to take over stocks of vital supplies from private companies
15. Administering needed therapy to nonmentally competent, institutionalized patients; prison inmates; etc.

Natural Disasters

The deaths of patients in hospitals submerged by floodwater in New Orleans, LA, by Hurricane Katrina in 2005 have highlighted the issue of physician responsibility to his or her patients in times of extreme natural disasters. The physician faces at least three dilemmas under such circumstances: (1) balancing personal, family, and col-

league safety with the duty to ensure patient safety and ongoing medical care, (2) providing adequate or at least life-saving care under conditions of severe infrastructure disruption, and (3) the responsibility to mitigate the consequences of disasters by adequate prior preparation for such emergencies. The most acute problem seems to be the immediate or even slightly delayed malfunction of life-sustaining equipment, such as ventilator shut-off due to lack of electrical power or oxygen, or dialysis machine dysfunction due to lack of electricity and dialysate. The lack of air-conditioning, degradation or destruction of stores of medicines, death, incapacitation or desertion of staff, destruction of all or parts of the medical facility, etc., may create an environment that renders the provision of adequate medical care impossible or tenuous.

What is, then, the duty of the physician under such circumstances? It seems futile to provide advice such as "patients first" or "save yourself and/or your loved ones first." It is the physician's duty to do his utmost, under the specific circumstances, to save the patient's life or prevent irreversible injury or organ damage. It seems reasonable to demand that any decision to withhold life- and limb-saving care should be taken only after due deliberation, discussion with peers and superiors, and, whenever feasible, documentation. Admittedly, sometimes the relevant time frame is extremely short (e.g., avalanche, tsunami), in which case it would seem that it is the physician's duty to save as many patients as is compatible with saving his own life. Finally, it is the duty of physicians (and managers, of course) to prepare the medical facility for disasters by appropriate planning, equipping, and staff training, in order to minimize or obviate some or all of these problems. Such mitigation activity is taken, by definition, prior to the event, and is therefore done under less or no time constraints. This makes the physician's duty in this respect much more binding, and any failure to fulfill it much less pardonable.

PITFALLS

The number and complexity of potential dilemmas are too numerous to address in their entirety in this chapter. Moreover, it is both impossible and unnecessary to have a policy for every situation that arises. Technical confusion, professional paralysis, and emotional numbing can seriously impair provider response, and even the classic codes of ethics fall short of a formulaic "one-size-fits-all" approach to moral challenges during mass casualty events.

Specific obstacles may be encountered before an event, during the event, and after the event. Professional ennui and lack of preparedness may be encountered at the individual and system levels. Ethical pitfalls during the event include all of those previously discussed regarding triage, resource allocation, safety, and fairness, as well as duty to care issues when the only contract is of the unwritten, Lockean, social contract variety. In the wake of an event, there are opportunities for fame and fortune and the chance to change practice.

However, there are overarching virtues and vices that can help or hinder a properly ethical MCI response,

respectively. Virtues inform a wide variety of behaviors well beyond the reach of most ethics codes, principles, and policies. Around 330 BCE, Aristotle made virtues the basis for all ethics and discussed in his famous *Nicomachean Ethics* that the exercise of virtue was properly the middle ground or “golden mean” between deficiency and excess. Courage, for example, is vital for a healthcare provider to respond bravely to dangerous disasters and MCI situations. Ill-tempered or overexuberant foolhardiness to rush into a contaminated area without proper personal protection equipment when the equipment is available is not considered courage; it is merely foolishness. At the other extreme of this spectrum is the frightened provider who is afraid to act, immobilized by fear. Courage is a willingness to respond in the throes of danger, and it demands that we bravely treat both the perpetrators and the victims of MCIs and have the inner fortitude to take a stand for moral principles when it is difficult or unpopular to do so. Saying “no” to esteemed members of society, family, and friends for the greater good; allowing expectant patients to die under austere conditions; enforcing quarantine and reporting provisions with friends and colleagues; willingly responding to the call for help without fear of malpractice threats, infectious disease exposure, or economic risk are all examples of courage in action.

Justice is vital to promote fairness and the proper allocation of scarce resources according to need. Justice also enjoins providers to adhere to the mandate of the World Medical Association’s Declaration of Geneva to treat patients regardless of “age, disease or disability, creed, ethnic origin, gender, nationality, political affiliation, race, sexual orientation or social standing.”⁴

Similarly, prudence, or sound judgment, is the practical wisdom required to weigh competing interests and apply technical and moral facts to particular scenarios. Determining who to triage, refer, transport, and decontaminate all require prudential wisdom.

Stewardship is similar to prudence because it requires common sense in using scarce resources. This has application to everyday health resource distribution, but it is especially important under the resource and time limitations of a disaster to use personnel and equipment optimally.

Vigilance was perhaps the virtue most evidently lacking on Sept. 11, 2001. Around-the-clock guardianship does not relax on nights, weekends, and holidays. Surveillance activities and MCI preparedness plans mandate an ever-ready, argus-eyed vanguard of medical personnel who are prepared and able to respond before they are ever activated in the field. “Closing the stables after the horses are free” is a meaningless gesture—too little, too late.

Although the foregoing discussion may readily suggest that prudence, courage, justice, stewardship, and vigilance are central for responding to and being prepared for disasters and MCIs, their opposites—impulsivity, cowardice, prejudice, profligacy, and procrastination—are dangerous pitfalls to avoid. As Thomas Aquinas pointed out many centuries ago, for every virtue there is an antagonistic vice that hinders its expression. One way to avoid these vices is to prospectively draft policies

and procedures that define role expectations that virtuous persons would manifest.

SOLUTIONS

Virtue, or character, is an important antidote to the many pitfalls and vices. The following principles for administering medical assistance amplify the core virtues of justice, prudence, courage, stewardship, and vigilance and take into account the tripartite obligations of medical professionals to patients, the profession, and the society in an MCI.

1. It is the ethical as well as the professional duty of society and the medical establishment to provide the infrastructure and timely local means to healthcare to minimize the disparity between demands and capabilities, thereby minimizing the number of casualties receiving suboptimal care, even in an MCI. At the same time, providers have parallel obligations to prudently manage and distribute scarce medical resources to avoid waste and to maximize the benefits for all victims.
2. It is essential to be prepared for a designated role in an MCI by continued study, drills, vigilance, and training, even in the face of financial and organizational constraints.
3. The principles of utility and justice mandate that care be distributed equitably and in a manner that maximizes survival and minimizes suffering for the greatest number of victims. Therefore, triage must be carried out fairly and without bias toward individual patients regardless of gender, age, race, creed, ethnicity, or role in the conflict. Medical and operational consideration should be the only factors determining the priority of care. The identity of the victim should play no role in decision-making, except in very extreme situations and those to be determined by policy set forth before the event.
4. Caregivers have a duty to treat MCI victims even in the face of personal danger. Balancing the needs of patients with the right of the caregiver to personal safety should be discussed and spelled out by the authorities before the event. Keep patients, other providers, and oneself safe to the extent that it is compatible with timely and efficient care of the majority of victims. Administer maximal amounts of medical care compatible with the operational limitations. At the very least, strive to minimize suffering.
5. Respect for patient autonomy, dignity, and right to privacy and to information are important even in an MCI. However, these rights may be subordinate to the exigencies of the situation when expeditious care for all patients is the first consideration.
6. Guard the identity, privacy, and confidentiality of victims of an MCI.
7. Work cooperatively with others who care for and about MCI victims and safeguard the public health.
8. Honor your profession by serving in an MCI without self-concern or demands for compensation or remuneration for service. Avoid opportunism and the lures of fame and fortune.

CONCLUSIONS

MCI and disasters introduce numerous ethical challenges in triage, resource allocation, and patient care at the microlevel (patient care), mesolevel (professional principles), and macrolevel (societal). Prospective consideration of these challenges, disaster drills, and development of ethical MCI policies and protocols can help medical personnel function in a manner compatible with most of the basic ethical principles that guide medicine. To guarantee widespread commitment, ethical MCI policies and procedures must be drafted in advance with the input of both medical leadership and the people delivering actual care in the field. The realities of MCI are difficult to comprehend for anybody who has not "been there"; thus, learning from the experience of those who have been personally involved in MCI and disaster care can benefit medical professionals in all parts of the world who are only now preparing for their first MCI.

Liability Issues in Emergency Response

Abigail Williams

Emergency response to a potential or actual catastrophic event has become more frequent and is now performed by a greater variety of organizations, including those whose sole mission is to respond to disasters and others who perform a variety of services, including disaster response. In the past, response from the Salvation Army and Red Cross to disasters and other large-scale events was common, anticipated, and accepted by the public. During the past 10 to 20 years, however, a greater number of more diverse agencies have routinely become involved in emergency response. In large measure, the plethora of media coverage has taught the public to expect that when an emergency situation occurs, the response will be professional, efficient, effective, and capable.

What has caused this enhancement of emergency response to occur? A number of factors have emerged, including, but not limited to, a quasi-government hierarchy that developed in part from the Civil Defense network of the 1960s. Local jurisdictions have emergency managers and emergency planning groups that may have staff and resources capable of emergency tracking, incident awareness, and rapid scene response. This structure builds both horizontally and vertically to include mutual aid from neighboring jurisdictions and from county, state, regional, and federal levels. This traditional structure is best represented at the primary level by local responders in law enforcement, fire, and emergency medical services (EMS). The Federal Emergency Management Agency (FEMA), as well as a variety of federal subteams, represent the next level of responders.¹ However, if the event involves an epidemic illness or chemical exposure, agencies such as the Centers for Disease Control and Prevention (CDC) and the Occupational Safety and Health Administration (OSHA), may respond. If there is a transportation incident, the National Transportation Safety Board (NTSB) and the Department of Transportation (DOT) may become involved. Where there is a terrorist event or crime involved in a disaster, the Federal Bureau of Investigation (FBI) and other law enforcement agencies, such as the Central Intelligence Agency (CIA) and the Bureau of Alcohol, Tobacco and Firearms (ATF), will also be part of the response and de facto command structure.

Parallel to this government response structure are other local and regional responders. Each of these agencies, although acknowledging the incorporation of the

Incident Command System (ICS) into its overall operations, has different command structures. These agencies may include search and rescue teams; critical incident debriefing teams; canine search resources; regional air medical (helicopter) programs; various utility and construction assets; supply and logistics resources; religious organizations; and other agencies, whether volunteer or paid or trained or untrained. Incident command, although implemented by a number of agencies, has been used throughout the United States in an inconsistent manner and is almost always cited in the after-action reports of emergency responses and drills as one of the processes that failed.²⁻⁸ In one of the most well-critiqued and available after-action reports from the 1993 World Trade Center bombing, the problems with the incident command structure and multijurisdictional and interagency response and communications were well documented.⁹ In the investigation of the Columbine High School shooting, it was noted in the section on “lessons learned” that: “Fire department communications were severely stressed at this operation Department communications capabilities must be established so that they can handle the largest of emergencies that could occur in their jurisdiction Our standard portable radio, tactical frequency was overloaded and ineffective. The same problems were encountered with the command channels.”¹⁰

Because of the lay publicity of these human resources and assets, response, in any perceived or real emergency situation, has become a public expectation in the United States. As a result of this expectation, the focus is now increasingly being placed on the timeliness and adequacy of that response. This paradigm shift in the public perception is reflected in great measure by a recent federal court decision involving the emergency response to the Columbine shooting. In the investigation of the Columbine High School shooting, it was found that standard fire department communication modalities were overwhelmed and therefore became ineffective.

The implication of that federal case for emergency responders is that they will now be held to a reasonable standard of care in the implementation and utilization of ICS. Any failure to act reasonably in the implementation of ICS may now result in responders being held liable for any injuries that are caused to victims under certain circumstances. The almost

blanket protection that government and municipal responders have relied on, which traditionally has been provided by the Good Samaritan and other qualified immunity statutes, has been eroded, and the right to reasonable emergency response under certain circumstances has been strengthened. The overall impact, theoretically, will be one of heightened awareness of the obligations of emergency responders during a response. However, the *Sanders* decision, on which this chapter is partly based, thus far has been unrecognized as having this effect on the emergency response system.¹¹

HISTORICAL PERSPECTIVE

The threat of malpractice litigation against EMS in relation to disaster response is almost nonexistent. There are no reported cases of successful lawsuits against disaster response providers for negligently providing medical care. However, questions regarding the adequacy of patient care and provider safety during a disaster response remain the topic of much controversy. The topic is most commonly raised in a number of specific situations:

- The first situation is one in which a responder becomes injured or dies during a response to a disaster. Such could have been the case when a young nurse, Linda Anderson, died while entering an unsecured area and attempted a rescue at the Oklahoma City bombing of the Murrah Federal Building.¹²
- The second situation is when a person believes that his or her civil liberties are being violated as a result of forced decontamination, quarantine, immunization, or isolation.
- The third situation is when the responder becomes injured due to the negligence of a third party.¹³
- The fourth situation is when a live victim is not cared for either properly or timely and dies from nonfatal injuries.¹¹ While attempting to evacuate students during the Columbine shooting, Dave Sanders, a teacher at Columbine High School was shot. Repeated calls to 911 were met with the response that help would come in 10 minutes. Unfortunately, no help came from noon until nearly 4 PM, when David Sanders died.¹¹

Typically, victims injured in a disaster commonly sue the agency responsible for the accident, which causes such disasters to draw attorneys as well as rescuers. At some point, attorneys are going to look not only at the primary cause of the victim's injury (e.g., the plane crash, train crash, building collapse, or bombing), but they also will consider any secondary injury sources. The key, therefore, is to enhance the coordination and quality of care provided by the emergency responders in response to a disaster and to ensure that all applicable laws, regulations, and standards of care are met.

ABOUT THE LAW

Although coordinated and dedicated emergency response systems are a fairly recent development in the delivery of healthcare, it is important to recognize that the laws that govern the legal liability of these services are far from new. In fact, these laws and rules come from a progressive development of case law, statutory laws, and regulations promulgated over centuries. The rules of law that apply to emergency responders, therefore, are a composite of traditional general rules, transportation law, and rules flavored with recent federal mandates. Understanding the source of the rules and the applications that have arisen over the years is essential to a consideration of legal liability and distinctions that have arisen for emergency response application.

Sources of the Law

The federal constitution and each state's constitution are the foundation of all laws and individual rights in the United States. These documents create legislatures that write laws, courts that interpret the laws, juries that determine facts, rights that the government must protect, and the executive divisions of governments that enforce the laws as interpreted by the courts. In the past half century, a new source of law has emerged—administrative regulations, which blur the distinction between the legislative and executive branches of government as it applies to the emergency responder liability discussion. However, constitutionally protected rights have seldom been used beyond whether a jury trial must be provided to determine a malpractice claim. That changes somewhat when one considers the need for governmental infringement of an individual's constitutionally protected rights, i.e., martial law, forced isolation, forced quarantine, and decontamination in certain circumstances during a disaster. The dominant source of law in the medical field has been the court system, specifically with its decisions on interpersonal rights and responsibilities and the jury system driving the price of liability. To a limited degree, legislatures have attempted to reform the court systems and limit liability in malpractice cases, but at the same time, increasing volumes of regulations create new standards that may become the basis for claims of malpractice liability.

Court Concepts

The courts of this country function on a number of basic principles, which are essential to understand in a discussion of legal liability for emergency responders and emergency care providers.

Venue

Most negligence cases are based on state standards and tried in state courts, unless a case involves "diversity of citizenship" (residents or services of different states involved), constitutional issues, or a claim arising out of the alleged actions of a federal employee. State law

determines the rights of parties to the case, the procedures they must follow, and the damages (money) or limits to damages they may recover.

State courts are typically organized according to county. Juries are normally selected from the community where the case is filed (venue). This is usually the county where the medical care occurred, but technicalities may result in a pitched legal battle over where the case must be tried to control which judge will preside over the case or the type of community from which the jury members will be selected. The venue for filing a case is often very important to the outcome or size, if any, of the verdict. In emergency response situations, the location of the care might involve more than one state or county and that may further expand the possibilities of where the case may be tried.

Case Law

Courts are expected to follow established precedent to the extent that it fits the case before that particular court. This is called *stare decisis*. The process of following these prior decisions is often referred to as “common law,” or “case law.”

The Role of the Court

The U.S. legal system is based on a respect of the roles of the various government branches. The legislature makes the laws, and the courts are to apply the laws as written. If an ambiguity exists in the language of the law, the courts are to interpret what the law means. Courts, however, have become more active in creating new rules and interpretations by distorting or expanding the language of the legislature, depending on the view of the critic.

A Hierarchy of Authority Exists

Not all sources of law are equal. There is a definite hierarchy of authority based on the source of the law being applied and the court system applying it. In most judicial systems, the highest court, usually the U.S. Supreme Court, issues decisions that control all of the lower appellate and trial courts in the system. The decisions of a state supreme court only control the courts of that state; decisions in other states may be influential, but they are not binding on another state. State appellate court decisions are generally binding only on trial courts within the subdivision controlled by the appellate court rendering the decision. Local level courts may have rules that regulate the procedures in the courts of that county. The decisions of a trial judge, however, only bind the litigants in the individual case. In the federal court system, the same hierarchy exists and the binding effect of the ruling is generally confined to the same federal structure, which is much like the state system. One exception is when the ruling provides an interpretation on the U.S. Constitution, and such a ruling typically is controlling at the federal and state levels. A similar exception would be in a case in which a federal law “pre-empts” or overrides state law. The federal court decision would control the federal courts below it and the state courts within its geographic, jurisdictional area. A different exception would apply in

the event that a state is a party to the lawsuit before the federal court. A ruling by the federal court would control the specific state involved in the case.

Role of the Trial Judge

The role of the trial judge is to rule on the law, the process, and the evidence in a case. The trial judge controls what issues are allowed to be presented by ruling on the legal sufficiency of various elements of court documents. The judge also controls what items of information the parties can have access to through the process of “discovery.”

During trial, the judge serves as the referee to ensure that both sides follow the rules of courtroom decorum. In addition, the judge rules on motions and objections that determine what evidence is presented and how it is presented. These rulings on evidence often have a profound influence on the ultimate outcome of a case. At the conclusion of the presentation of evidence and after attorneys for both sides have presented closing arguments, the judge gives a verbal “charge” to the jury. This is a reading of the written instructions that jury members will use while deliberating the verdict. The outcome of many cases hangs on the precise wording of these instructions.

After the verdict is given, the trial judge may rule on motions for a new trial or to overturn the verdict of the jury. These post-trial motions are usually in preparation for an appeal to a higher court. Once an appeal is filed, the trial judge loses jurisdiction over the case unless the higher court returns the case with instructions or rulings.

The Role of the Jury

Most states in the United States and all federal courts allow either side of a negligence case to request a jury trial. The number of jurors may vary by locality or jurisdiction. Different courts follow different procedures for selecting jury members from the pool of potential jurors. The cost and complexity of a case increase dramatically when a case is tried before a jury rather than having the case tried before a judge without a jury (bench trial), but the overwhelming majority of negligence cases are jury cases.

The jury members sit through the trial, listen to the witnesses’ testimony, view the physical evidence, consider the arguments of all the attorneys, and are charged to follow the law given to them in the judge’s instructions. The jury must reach its decision in any case based on what facts it finds to be true by a preponderance of the evidence. This means that the jury must be convinced that a given fact is more likely true than untrue, or just beyond 50% probability. The jury is considered the “conscience” of the court system. It is charged with the duty to render its decision based on the facts, evidence, and law presented to it, without allowing sympathy or prejudice to interfere with the process.

Standard of Care

Often, the most significant fact that the jury must determine is whether the emergency responder’s care in the

case was within the “standard of care.” This essentially is a determination of whether the emergency responder “negligently injured” another person(s) in some way, as claimed in the lawsuit.

A standard of care may be created by a law, regulation, case law, or testimony on the standards observed by emergency responders of the same type. For example, alleged failure to appropriately use the ICS formed the basis of a lawsuit against municipal emergency responders to the Columbine shooting. Generally, to prove negligence, an expert of the same responder specialty must testify that the care provided did not meet the “standard of care” expected in similar circumstances. The “standard of care” definition varies by state, but in concept, it is the minimally acceptable level of competency and care expected of a responder of the same type acting in the same circumstances.

Although the court often makes legal rulings on issues that may affect what facts go to the jury, we will consider the concept of liability for negligence claims as presented in the following, based on four factual elements that the jury generally determines:

1. **Duty:** Did the emergency responder establish a relationship with the patient that created a duty?
2. **Breach:** Did the emergency responder fail to effectuate that duty in a manner that fell below the standard of care of the specialty or profession?
3. **Injury:** Did the action or inaction of the emergency responder that failed to meet the standard of care cause a legally recognized injury (physical, psychological, property damage, or damage to another legal right), worsen the injury, cause or increase expense, or (in some states) reduce the chances for a favorable outcome? Was there a logical connection between the failure to meet the standard of care and the resulting injury?
4. **Damages:** What award of money will compensate the victim for the injury or losses suffered and reasonably likely suffer in the future? This typically includes medical expenses, hospitalization, home care, loss of wages, and pain and suffering sustained.

This issue of standard of care will reappear frequently throughout the following discussions of emergency response liability.

BASIC CONCEPTS OF LAW THAT APPLY TO EMERGENCY RESPONSE

First and foremost in any healthcare-related law is the concept of patient choice as a fundamental right. The competent, unimpaired adult has the right to choose (or refuse) whatever medical treatment he or she will receive, even if that choice might otherwise seem illogical or may result in death. Persons who are unable to consent due to injury or medical condition, intoxication, mental illness, or legal incompetence are presumed to consent to care reasonably necessary under the concept of “implied” consent. In an emergency, the “emergency exception” allows care, rescue, and decontamination to be provided without obtaining consent. This issue

becomes important when one considers that in the event of nuclear, radiological, chemical, or biological contamination, people will be required to be decontaminated, isolated, and possibly quarantined for a period. For public health and safety reasons, they will not have the option of refusing such care. Even though some organizations recognize the right of an individual to refuse care under emergency circumstances, the majority of emergency response organizations advise that no person who has been contaminated should leave an area without being decontaminated, unless that person is critically injured and transported to a hospital for emergency medical care and subsequent decontamination. This raises one of two options. The first is to allow the person to remain in the contaminated area at his or her own peril, which the person will unlikely agree to do. The second is to decontaminate the person against his or her will, which may lead to various claims of restraint, battery, false imprisonment, etc. It is critical to emphasize that the response to allegations of criminal or constitutional violations, arising out of the involuntary treatment of an individual, is for the purpose of mass decontamination, isolation, and quarantine in a contamination incident and to prevent the spread of the contaminant and thus avoid a significant public health disaster. In such cases, the rights of the individual are superseded by the obligation to the rights of the many.

Consent may be legally obtained from a competent, unimpaired adult for his or her own care; however, issues frequently revolve around who may consent when a minor is involved. For the purposes of this chapter, the emergency exception to the requirement of consent will always apply and rescue care and other emergency response services must be provided with or without formal consent and may even be provided in the presence of an expressed refusal.

REGULATORY VIOLATIONS

The rules that apply to regulatory violations and their effect on liability vary from state to state. In some states, when regulatory violations occur and harm results, normal medical malpractice may be established without resorting to experts to establish the standard of care. This approach is called a “per se” standard—the violation is automatically conclusive proof of negligence. Other states use a “prima facie” rule that shifts the burden to the defendant to prove that the violation of the regulation was not negligence. In either case, however, there must be resulting harm to the patient for liability to exist.

Not every violation of regulations would result in liability. If the maintenance regulations were not being properly complied with, it would not be grounds for a negligence claim, but it may form the basis for a criminal or administrative complaint. In the absence of explicit intent of the legislature or government agency to create a safety standard or the absence of prior court rulings on the issue, it is up to the injured party to prove to a judge that the regulation is a safety standard that should be applied to create liability.

WHEN CIVIL LEGAL LIABILITY ATTACHES

The question that commonly follows a description of this concurrent and overlapping medical response is, “When does *legal* liability attach—or detach?”

The answer to that question is: Legal liability flows to any identifiable person for emergency response. Even though U.S. citizens may assume that during a disaster emergency, response services will provide competent and trained scene stabilization, search and rescue, medical care, and transport services, these are not articulated constitutional rights. Nevertheless, persons who are called on to respond to disasters or who may volunteer to do so must understand how to provide safe and effective care and not succumb to the mantra that “there are no rules in a disaster.” Although unpredictability is characteristic of disasters, many types of disasters recur with regularity, resulting in a body of research, called *disaster epidemiology*. Disaster epidemiology allows for retrospective data collection and analysis of similar types of disasters and prospective consideration of the best practices in similar types of disaster management.¹⁴

The analysis that a Colorado court went through regarding the Columbine shooting case in determining whether any liability attached to the actions of the Jefferson County Sheriff’s department articulates the basis of the nonconstitutionally based quasi-establishment of a “right” to emergency response in a disaster.¹¹ The court noted that central to the question of liability of responders (in this case municipal) is the primary consideration of whether there is a recognized “right” on the part of any particular individual to emergency response. The court reviewed the traditional legal test by which a right is determined by first determining whether there was a “generally applicable right protected under the Fourteenth Amendment of the U.S. Constitution.” The Fourteenth Amendment states in part that¹⁵:

Every person who, under color of any statute, ordinance, regulation, custom, or usage, of any State . . . subjects, or causes to be subjected, any citizen of the United States . . . to the deprivation of any rights, privileges, or immunities secured by the Constitution and laws, shall be liable to the party injured in an action at law, suit in equity, or other proper proceeding for redress.

Accordingly, the *Sanders* court reasoned that this section, enacted in its original form in 1871, was “specifically drafted to provide a method for an individual to seek redress of violations of their rights so protected under the Fourteenth Amendment by any person or group of people who act on behalf of the state.”¹¹ The court acknowledged that the framers of this amendment apparently contemplated it to provide a method of redress under specific circumstances, those being the willful, knowing, or purposeful deprivation of life, liberty, or property by state action. It has been held by most courts and was articulated by the *Sanders* court that “the Fourteenth Amendment does not specifically serve to transform tortious conduct into a constitutional violation.”¹⁶ Instead, the *Sanders* court noted that the Fourteenth Amendment does somewhat serve to protect citizens from the “arbitrary, abusive, or oppressive use” of

government (state, local, or municipal) power.¹⁵ This basic principle articulated by the *Sanders* court when defining the basis for the right to assistance in an emergency was that the Fourteenth Amendment does not confer an “affirmative right to governmental aid, even where such aid may be necessary to secure life, liberty, or property interests of which the government itself may not deprive the individual.”¹⁷ As a result, the court noted that any specific individual has no affirmative constitutionally based right to emergency response under ordinary circumstances.¹¹ Thus, in the general sense, no one person can in an ordinary circumstance sue a government or municipal responder (or private responder) for injuries that occur as a result of a rescue, failure to rescue, or other emergency response activity, providing that the actions taken were in accordance with the identified standard of care.

Specifically, the *Sanders* court in its decision announced that even the U.S. Supreme Court has held that the due process clause of the Fourteenth Amendment “does not impose a Constitutional duty upon a state to protect individuals from violence, fire, or other need for emergency medical response.”¹⁷ Relying on previous decisions from other courts, both state and federal, the *Sanders* court stated that the due process clause actually “serves as a limitation on the state’s power to act, not as a guarantee of certain minimal levels of competent or effective safety and security.”¹¹ Again, as noted in this case, the court relied on prior decisions but had also accepted exceptions to the general rule of “no duty,” which creates some concern for emergency responders.¹⁸ The court relied on the recognition of the “special relationship doctrine” and the “state created or enhanced danger doctrine,” discussed in the following section, as potential vehicles for affording redress to an individual who has sustained an otherwise compensable injury as a result of actions or inactions of emergency response personnel.¹¹

NATURE OF THE LEGAL OBLIGATION OF RESPONDERS TO AN EMERGENCY

The Special Relationship Doctrine

The “special relationship doctrine” adopted by the courts is well established and universally accepted. This doctrine only applies in situations where the state, municipal, or other government agency imposes limitations on an individual’s “freedom to act on his own behalf and therefore protect himself from harm.”¹¹ Examples of this limitation occur in cases such as the institutionalization of a psychiatric patient; restraint of movement, such as when one is in handcuffs or restrained for his or her protection for the purposes of medical treatment during necessary transport; or during periods of incarceration (isolation and quarantine).¹⁹ Thus the court notes: “it is the governmental restriction of freedom that triggers the exception to the Fourteenth Amendment right, and not the creation of a Constitutional right to the protection in and of itself.”²⁰ The courts have noted that over the years there has been much wrestling with the definition and interpretation of specifically what level of restraint,

“similar” to incarceration or institutionalization, is sufficient to give rise to a state’s duty to protect a specific individual. Most jurisdictions, such as the Federal Tenth Circuit in Colorado, have adopted the requirement that an injured party must show involuntary restraint by a government official to establish a duty to protect under the special relationship theory.²¹ As a nonprivate sector (municipal) emergency responder or as a private responder acting under the direction of a government agency, liability will attach once some form of involuntary restraint occurs, such as isolation, quarantine, forced decontamination, perimeter shutdown, or forced sequestration during an emergency. If, as an emergency responder, one decides to restrain an individual or group of individuals, that responder or responder group is then reasonably responsible for the individual’s or group’s protection.

Thus the *Sanders* court acknowledges that the “special relationship theory” exception, when taken a step further, would logically result in the acknowledgment that “inaction by the state or state-directed entity absent involuntary restraint even in the face of a known danger is not enough to trigger a Constitutionally based ‘duty to protect.’”¹¹ That is, of course, unless the state or state-directed entity has a custodial, restrictive, or other special relationship with the person who claims lack of protection resulting in an injury. The courts have uniformly taken the position, as noted in the *Sanders* case, that any affirmative duty to protect an individual must arise from the limitation of movement that is imposed on the individual’s freedom to act on his or her own behalf. It is not simply the responder’s knowledge of the individual’s actual or potential predicament that controls, but rather it is a “restraint” or limitation on movement that controls. Moreover, it is accepted that an emergency responder’s knowledge of the risk of harm to another is not relevant to the determination of whether a special relationship between the parties in fact existed. Even under circumstances in which the emergency responder can reasonably foresee a reasonable likelihood of harm from inaction, “an affirmative duty to protect is not created unless or until the injured party can prove that a custodial relationship limiting his or her ability of self-protection did in fact exist.”²²

State Created or Enhanced Danger Doctrine

The second exception to the general rule that the government entity has no duty to protect any individual citizen from private violence is the “state created” or “enhanced danger doctrine.”¹¹ Courts across the country have considered the question of just what state conduct “creates or enhances” danger sufficient to establish a duty to protect.²³ Some courts have decided, for example, police officers who engage in a high-speed car chase resulting in injuries to a bicyclist, motorist, or pedestrian could be legally responsible for creating a special danger faced by the injured party. Clearly the door has been left open for government liability where the state creates a dangerous situation or renders citizens more vulnerable to danger.²⁴ It is therefore accepted that the environment

created by state actors must actually be dangerous; they must actually know it is dangerous; and to be liable, they must have used their authority to create an opportunity that would not have otherwise existed. “If the danger to the plaintiff existed prior to the state’s intervention, then even if the state put the plaintiff back in that same danger, the state would not be liable because it could not have created a danger that already existed.”¹¹ If the alleged injured party fails to prove some form of affirmative action by the defendants that created or increased the danger to the individual victim, courts have universally dismissed the plaintiffs’ complaints.¹⁸ Under the Uhlrig test, to determine whether a government entity has created or enhanced a danger for the injured party, the following must be proved¹⁸:

1. Whether the injured party was a member of a limited and specifically definable group
2. Whether the emergency responder’s conduct put the plaintiff at substantial risk of serious, immediate, and proximate harm
3. Whether the risk to the injured party was obvious or known
4. Whether the emergency responder acted recklessly in conscious disregard of that risk
5. If such conduct, when viewed in total, “shocks the conscience” of federal judges

An injured person must also show that the state entity and the individual emergency responder created the danger or increased the danger in some way.

LEGAL PROTECTION FOR EMERGENCY RESPONDERS: CURRENT PRACTICE

Volunteer Protection Act

In 1997, President Clinton signed into law the Volunteer Protection Act of 1997 (VPA) in an effort to provide some immunity from liability for claims that are made against volunteers who are providing services under the auspices of not-for-profit organizations.²⁵ This law preempts any state laws “to the extent that such laws are inconsistent with the Act” so that any state that chooses to have a law that is more protective than the VPA may, but any state that offers less protection is preempted by the VPA. The VPA does require, however, that some provisions be written into state law, including the requirement that the not-for-profit entity has risk management procedures in place and a provision for vicarious liability of the not-for-profit organization for the acts of a volunteer. Essentially what the VPA serves to do is to provide a qualified immunity for volunteers who are providing services for a not-for-profit organization under certain circumstances. To claim the benefit of this qualified immunity, the following circumstances must exist. The VPA provides immunity from lawsuits filed against a not-for-profit organization’s volunteer when the claim is one of carelessness or traditional negligence. It is critical to note that the act does not provide immunity to the organization itself. The law only protects individuals who are acting in a volunteer capacity on behalf of a not-for-profit entity and preempts

state laws that might hold a volunteer personally liable. The VPA only applies to uncompensated volunteers who provide services to appropriately designated 501(c)(3) and 501(c)(4) not-for-profit organizations. The immunity is a qualified immunity and protects the volunteer only against claims of ordinary negligence and not against claims of gross negligence; willful, wanton, reckless, behavior; or criminal misconduct. Any conduct that is intentional, conscious, or demonstrates a flagrant indifference to the rights or safety of the individual harmed is not covered by the VPA.

The VPA includes a provision that, if taken advantage of, ensures that innocent third parties hurt by the carelessness of not-for-profit organization volunteers will be adequately compensated for their injuries while, at the same time, providing personal immunity to such volunteers. This part of the act allows a state to require that a charitable organization “provide a financially secure source of recovery for individuals who suffer harm as a result of actions taken by a volunteer on behalf of the organization” before its volunteers gain immunity under the act. A general liability policy with adequate limits would be considered a financially secure source of recovery.

Qualified Immunity Statutes

At the core of qualified immunity is objective reasonableness. As long as the actions of the emergency responder, viewed from the perspective of the responder at the time and under the same or similar circumstances, can be determined to be within the range of reasonableness, then no liability will attach. Federal disaster medical assistance teams (DMATs) also have government immunity because when they are deployed and are providing care in a disaster environment, they are considered to be federal entities employed by the federal government for the specific purpose of an identified emergency response. Some argue that Good Samaritan and other immunity statutes provide blanket protection for the “best they can do under the circumstances” medical care in these emergency or disaster situations and therefore promote volunteerism during times of great need. Many questions have been raised, however, regarding the adequacy of such protection and immunity when disaster response is an expected, trained for, and perhaps even specialized, aspect of emergency response. Although it has been convincingly argued that the Good Samaritan and other immunity statutes and laws, as they are applied in disaster response, are of significant benefit, it is interesting to note that there are no studies to date that prove the theory: It is the threat of liability that prevents volunteers from acting. The other side to this blanket protection is that it can serve to open the door for substandard practice during a disaster response because there is no fear of legal repercussion for failure to act in a reasonable manner. Government responders, such as municipal fire, police, and EMS, have a number of limits on their legal liability. For one, there is no recognized right to an emergency response, and thus if no response occurs, there is no liability. The Federal Tort Claims Act (FTCA)²⁶ allows the federal government to be

held liable for the negligent acts of its employees, providing that the care that is in dispute is performed within the course and scope of their duties. This is in contrast to the general rule that the federal government has absolute immunity from liability. Thus, under the FTCA, the federal government can be held liable in the same circumstances as a private person in accordance with the law in the jurisdiction where the care occurred. The FTCA does limit the type and amount of damages that can be recovered under its umbrella and sets up some procedural hurdles for bringing claims. It should also be noted that there are exceptions to the waiver of immunity that is addressed in the FTCA. There is a specific prohibition against bringing any claims for damages that are caused by the imposition of quarantine, based on acts or omissions during the execution of a statute or regulation, provided that there was an exercise of due care or discretionary function. Other federal acts that address immunity for emergency management and consequence management are the Robert T. Stafford Disaster Relief and Emergency Assistance Act and the Homeland Security Act.²⁷ Even though these statutes serve to protect the government and responders from liability, a showing of recklessness, negligence, or bad faith may pierce them. The Military Claims Act serves to compensate for personal injury or death resulting from military service. This act covers claims that are brought for negligent acts or omissions against a federal employee who is acting within the scope of his or her duty and claims that are based on noncombatant activities of the military, such as training exercises. Similar types of immunity statutes exist on state and municipal levels.

The basic principles of qualified immunity, as previously noted, are well settled, and the purpose of an immunity statute is to limit the deleterious effects that the risks of civil liability would otherwise have on government operations at all levels.²⁸ It has been well settled by the courts that discretionary decisions such as emergency management and response by government agents inevitably influence the lives of private individuals, sometimes with harmful effects despite the best of intentions and rigorous attention to practice.¹¹ Moreover, decisions made in an emergency are understandably and to some extent inescapably imperfect.¹¹ In the context of emergency management, decisions must be made in an atmosphere of great stress, haste, and uncertainty. Holding emergency responders liable in hindsight for every injurious consequence of their actions would only have a chilling effect on the functions of emergency response. Qualified immunity thus allows state, municipal, and federal emergency responders the freedom to exercise fair judgment, protecting “all but the plainly incompetent or those who knowingly violate the law.”³¹ In summary, although there seems to be growing potential for liability, there are only limited circumstances under which a government, municipal, or private emergency (in some states) responder may be held individually liable for negligence that results in injury to another. To prove negligence, there must either be a “state created danger,” a “special relationship,” or conduct so negligent that it constitutes willful, reckless conduct that triggers such a duty of response.

PITFALLS

1. Assuming that there are no rules in a disaster
2. Failing to plan for emergency response to a disaster
3. Assuming that one cannot be sued because of Good Samaritan or other qualified immunity statutes
4. Acting outside the scope of one's license or certification
5. Failing to make a change in response to identified problems
6. Failing to critique each response and identify opportunities for improvement
7. Treating "lessons learned" in any given emergency response or drill as an oxymoron
8. Failing to adopt and practice an integrated ICS

chapter 11

Disaster Response in the United States

Jerry L. Mothershead

Response to emergencies and disasters for the protection of life, health, safety, and the preservation of property is a government responsibility. In the United States, governors, not the president, are primarily responsible for the health and welfare of their respective citizens and possess broad “police powers” that include the various legal authorities to order evacuations, commandeer private property, require quarantine, and take other actions to protect public safety.¹ Emergency response is carried out by local government entities within defined jurisdictions (e.g., towns, cities, counties). State governments coordinate needs identified by local governments with resources available either at the state or federal level.

In this chapter, the evolution of emergency and disaster management in the United States is discussed and an overview of disaster response as currently practiced in this country is provided.

HISTORICAL PERSPECTIVE

The Early Years: 1776–1945

The first recorded involvement of the federal government in disaster response dates to 1803, when the state of New Hampshire requested funding assistance after a series of devastating fires.

During the ensuing 150 years, response to major emergencies and disasters by government entities above the local level can only be characterized as reactive. Typically, a significant event would occur, outside resources would arrive from neighboring communities, and the event would be contained. Recovery operations were often slow, prompting requests to state governments for economic assistance. Only when the state was unable or unwilling to assist these local communities would the federal government become involved. At that point, federal legislation was usually required to authorize the expenditure of supplemental funds to assist the state and community involved.

Certain disasters occurred with greater frequency than others, and when the frequency and severity became significant enough to draw national attention, Congress would establish an office or agency to address

these types of events. Thus, during the first half of the 20th century, the Reconstruction Finance Corporation was established to make disaster loans after certain types of disasters. The Bureau of Public Roads provided funding for transportation infrastructure damage. The Flood Control Act, which gave the U.S. Army Corps of Engineers greater authority to implement flood control projects, was also passed. This uncontrolled and disorganized approach remained in effect until after World War II.²

Civil Defense Era: 1945–1974

The development of modern emergency management began in the 1950s with the passage of two pieces of federal legislation: (1) the Civil Defense Act, aimed at funding initiatives that prepared for civil defense against enemy attack (shelter programs, packaged disaster hospitals) and (2) the Disaster Relief Act, which provided funds to state and local governments for rebuilding damage to public infrastructure.³

During the 1950s and much of the 1960s, civil defense from enemy attack was the federal government’s priority, particularly the threat from nuclear attack that the Cuban Missile Crisis exemplified in 1961. At the same time, state and local governments were contending with significant natural disasters, such as the Alaskan earthquake (1964) and Hurricanes Betsy (1965) and Camille (1969). Federal funding for civil defense greatly outweighed that provided for natural disasters, and federal requirements prohibited the use of civil defense funds for preparedness to natural disasters.

At about this time, research and guidelines for disaster response started to appear. Severe wildland fires in southern California in the early 1970s gave rise to the congressional-funded project, Firefighting Resources Organized for Potential Emergencies (FIREScope), which developed the Incident Management System (IMS) concept. The first standards for disaster management were authored by the National Fire Protection Association (NFPA) and were aimed at healthcare facility preparedness (J. Kerr, personal communication, Ottawa, Canada, 2000).

The “first assessment” of disaster research occurred in 1975 and summarized the findings of the disaster research community.⁴

Coordinating State and Federal Response: 1974–2001

Throughout the 1970s, the National Governor's Association (NGA) called for streamlining the fragmentation of federal civil defense and disaster assistance programs. In 1974, Congress passed the Robert T. Stafford Disaster Relief and Emergency Assistance Act, which unified federal funding of civil defense and disaster assistance programs.⁵ In 1979, President Carter established the Federal Emergency Management Agency (FEMA) to serve as the overall executive branch coordination agency for disaster response.⁶ Parallel efforts at the state level resulted in the establishment of either a state Emergency Management Agency or offices with similar coordination functions.

The creation of FEMA and promulgation of various executive orders during the 1970s and 1980s improved overall federal response, but in general, authorities and responsibilities remained confusing and, on occasion, contentious. In an attempt to resolve many of these conflicts and promote a coordinated approach to disaster response, the Federal Response Plan (FRP) was developed to serve as the principal organizational guide for defining the roles and responsibilities of 26 federal member agencies and the American Red Cross, which are in charge of delivering emergency assistance during major crises.⁷ Although revised several times, the FRP did not solve all response and coordination problems and, in reaction to various disasters, additional federal plans were developed, including the Federal Radiological Emergency Response Plan (FRERP) and the National Oil and Hazardous Substances Pollution Contingency Plan, more commonly referred to as the National Contingency Plan (NCP).

Problems other than coordination continued. One example was the often significant delay in the arrival of state and federal response resources. The NGA successfully lobbied Congress to enact the Emergency Management Assistance Compact (EMAC)⁸ legislation, the first significant alteration to model state Civil Defense legislation passed in the 1950s. This legislation established a template for state-to-state resource sharing during disaster response.

Thus, by the turn of the century, the framework existed at the state and federal levels for coordinated response and recovery operations to disasters caused by nature or as the result of technological mishaps. Unfortunately, a new threat loomed that would again result in a major revision of the approach to disaster management.

New Millennium, New Threats: Post-2001

Terrorism arrived in the United States in the 1990s, with the first attack on the World Trade Center in 1993, followed by the bombing of the Murrah Federal Building in Oklahoma City in 1995. Internationally, terrorist organizations were growing in numbers, and terrorist acts were becoming more lethal. In addition to conventional weapons, these organizations were using chemical, biological, and radiological agents to cause

greater harm and were turning these threats against civilians as well as the political or industrial figures attacked in the past. The Aum Shinri Kyo religious sect used the nerve agent sarin unsuccessfully against several magistrates in Japan in 1994 and in the following year successfully attacked passengers in a Tokyo subway station. U.S. interests were increasingly under attack overseas, evidenced by dual embassy bombings in Africa in 1998, which were followed by the maritime attack on the destroyer *USS Cole*.

These events drew the attention of both the executive and legislative branches of the federal government. Under the Clinton administration (1992–2000), there was a promulgation of a series of executive orders, referred to as Presidential Decision Directives (PDDs), and the enactment of federal statutes to increase the defensive posture of and to protect the United States and its citizens against terrorist attacks. A number of new offices and programs were established in federal agencies, including in the departments of Justice, Health and Human Services, and Defense. The most significant legislation was the Defense Against Weapons of Mass Destruction Act,⁹ commonly referred to as the Nunn-Lugar-Domenici legislation. One of the Act's many purposes was to provide resources for equipment and the training of local response personnel for mitigating a weapons of mass destruction (WMD) incident.

These initiatives, while significant, proved insufficient to prevent the terrorist attacks that totally destroyed the World Trade Center in New York, significantly damaged the Pentagon, and resulted in nearly 3000 deaths on Sept. 11, 2001. One month later, weaponized *Bacillus anthracis* (anthrax) spores were distributed through the U.S. mail system, resulting in 11 deaths and another 11 infected persons. In combination, these events have resulted in some of the greatest restructuring of the federal government since its inception.

CURRENT CONCEPTS OF DISASTER RESPONSE

The terrorist events of 2001 sent shock waves throughout the U.S. government. New legislation was introduced in the first three months after the attacks that surpassed all antiterrorism legislation of the previous decade. President Bush, who had been recently elected, issued and continues to issue new and revised executive orders, now termed Homeland Security Presidential Directives, that call for changes in executive branch agencies to meet the current threat against terrorism. Funding to fight the "global war on terrorism" at home and abroad increased by a full order of magnitude and does not include the expenditures to fight the wars in Afghanistan and Iraq.

To best understand the emergency management system in the United States, it is important to first realize that all levels of government have certain roles and responsibilities in mitigation, preparedness, response, and recovery and that various government entities have different functions in preparedness and response.

Regardless of the government level, however, the designated emergency management agency is responsible for day-to-day coordination of mitigation and preparedness activities involving agencies and organizations at that level and for synchronization of these agencies during response and recovery phases. The designated emergency management agency also serves as the focal point for hierarchical coordination between local, state, and federal response agencies.

Local Level Emergency Management

Because there are subordinate jurisdictions within each state that are usually established by geographic boundaries, local emergency management may occur at the city, township, borough, county, or (in some states) parish level. To a great extent, the attention given to emergency and disaster preparedness and response will be dictated by the overall population within the jurisdiction, actual or perceived threats to the area, and population concentration. Ultimately, however, emergency management comes down to funding.

Regardless of the type of jurisdiction, an executive/managerial official will be in charge of emergency management operations. This official may be the community safety official, the fire chief, or the police chief. It is this individual's responsibility to form a multicentric organizational model within the community that brings together the disparate response and recovery organizations, including entities such as hazardous materials teams; fire services; law enforcement agencies; city, county, or district health departments; and public works departments.

State Level Emergency Management

All 50 states and the six territories have emergency management agencies that fall under the executive branch of the state government. In most cases, these agencies are either independent entities or increasingly are incorporated into the agency responsible for the state's National Guard. State Emergency Management Agencies (SEMAs) are responsible for standards, training, and oversight of emergency management organizations at lower jurisdictional levels; coordination with other state level agencies and organizations in their preparedness and planning activities; and the administration and distribution of state or federal funds earmarked for emergency management. In some states, disaster-related organizations, such as the state emergency medical services (EMS) office, are part of the SEMA, but this subordinate organization is by no means uniform across the states.

During response and recovery operations, SEMAs usually provide overall operations and support at state level emergency operations centers, provide liaison personnel to federal coordinating officers (the on-scene federal emergency manager), receive requests for assistance from local EMAs, and provide state level resources (both personnel and material) and expertise to local emergency managers.

In addition to its own resources, a state could request outside assistance from other states that are an EMAC signatory. Although, initially, few states signed on to this

agreement, in the wake of the terrorist attacks of 2001, almost all states and territories have now signed this legislation. Under an EMAC, a requesting state may ask for resources and personnel from a signatory state. If available, the assisting state will provide those resources, with the understanding that the requesting state will provide appropriate legal coverage from assisting personnel and will reimburse the assisting state for resources used. Depending on the actual wording and annexes of individual EMACs, such resources could include the National Guard or medical personnel who are not state employees.

Finally, a number of states, particularly in the Northeast, have signed international EMACs with provinces in Canada to allow resource sharing across the border.

Federal Level Emergency Management

With the rare exception of a disaster that meets the criteria of a national security event, coordinated federal response to disasters usually does not occur unless the governor of the affected state requests a presidential declaration of a national disaster, which then must be approved. However, each federal agency that could be involved in disaster response is still able to exercise its autonomy and respond directly to a request for assistance outside this coordinated federal response. For example, the Environmental Protection Agency could provide expert assistance during clean-up operations from an oil spill that did not meet national emergency thresholds. Similarly, the Centers for Disease Control and Prevention could mobilize one of its Epidemiological Investigative Service teams to assist in the evaluation and containment of a contagious disease outbreak. Under these circumstances, however, the funding stream to reimburse the agencies would fall outside that which is established for presidential declarations and may have to be through either state or agency resources.

Department of Homeland Security

Because of its pivotal role in overall federal level emergency management, one must understand the current organization and functions of the Department of Homeland Security (DHS). DHS initially was authorized to serve an advisory role to the president; however, a shift toward the concept of "Homeland Security" evolved, and through Congressional efforts DHS became the federal entity focused exclusively on this issue. In November 2002, the president signed into law H.R. 5005,¹⁰ the Homeland Security Act of 2002, which established the DHS¹¹ as a cabinet level executive agency. DHS consolidated 22 agencies and 180,000 employees, unifying many federal functions into a single agency dedicated to protecting America. Agencies under the DHS include the newly created Transportation Security Administration, the U.S. Coast Guard, and FEMA. FEMA's traditional role as the lead coordinating agency for all disaster response in the United States continues, but under the oversight of DHS. The secretary of DHS was given extraordinary powers, including the authorization to initiate a federal response under the Stafford Act without prior consultation with the president under certain exigencies.

DHS is organized around four principal functional directorates and a supporting, management directorate:

- The science and technology directorate coordinates the department's efforts in research and development, including preparing for and responding to the full range of terrorist threats involving WMD.
- The information analysis and infrastructure protection directorate assesses intelligence information concerning threats to the homeland, issues warnings, and takes appropriate preventive and protective action.
- The border and transportation security directorate is responsible for maintaining the security of borders and transportation systems and is home to agencies such as the Transportation Security Administration, the former U.S. Customs Service, the border security functions of the former Immigration and Naturalization Service, Animal and Plant Health Inspection Service, and the Federal Law Enforcement Training Center.
- The emergency preparedness and response directorate ensures that the United States is prepared for and able to recover from terrorist attacks and natural or technological disasters. FEMA was incorporated into this directorate in 2003, but retains its name and, to a certain degree, its autonomy, especially during response operations.

All responses to disasters and emergencies that reach the threshold for a presidential declaration of a national disaster fall under the coordination purview of DHS. Under these circumstances, FEMA is the operational arm of DHS in executing response and recovery initiatives and does so within the framework of two recently promulgated documents, the National Response Plan (NRP) and the National Incident Management System (NIMS).

National Response Plan. On Feb. 28, 2003, the president issued Homeland Security Presidential Directive #5¹² to enhance the ability of the United States to manage domestic incidents. To implement this directive, the secretary of DHS directed that a single, integrated federal Emergency Operations Plan (EOP) be developed. This NRP¹³ parallels the earlier NRP in format and links the following hazard-specific EOPs:

- FRP¹⁴
- U.S. Government Interagency Domestic Terrorism Concept of Operations Plan¹⁵
- FRERP¹⁶
- Mass migration response plans
- National Contingency Plan¹⁷

Under the NRP, FEMA serves as the overall coordinator for federal support. However, under the NRP construct, support is considered to fall within 15 different Emergency Support Functions (ESFs), which are listed in Table 11-1. Because resources and expertise in these various functions may exist within multiple federal agencies, each ESF response is coordinated by an ESF coordinating agency; a primary agency, which is usually the same as the coordinating agency; and a number of secondary (supporting) agencies.

TABLE 11-1 EMERGENCY SUPPORT FUNCTIONS

ESF NO.	FUNCTIONAL AREA
1	Transportation
2	Communications
3	Public works/engineering
4	Firefighting
5	Emergency management
6	Mass care, housing
7	Resource support
8	Public health and medical services
9	Urban search and rescue
10	Oil and hazardous materials
11	Agriculture and natural resources
12	Energy
13	Public safety and security
14	Recovery and mitigation
15	External communications

In the event of a national disaster, various emergency operations centers and oversight and policy entities will be activated at the headquarters level, not only of the DHS but of other federal agencies. The principal headquarters office responsible for interacting with state/local operations managers is the Regional Response Coordination Center (RRCC). At the local/regional level, the principal coordinating office is now termed the Joint Field Office (JFO). The JFO provides a local coordination of federal, state, local, tribal, nongovernment, and private-sector response organizations, and, in addition to federal, defense, and state field officers, is staffed by representatives from appropriate ESF coordinating agencies and other state representatives.

National Incident Management System. Homeland Security Presidential Directive #5 (an executive order) called for the creation of a standardized incident management system to facilitate interoperability and integration among the many federal, state, and local response organizations. NIMS¹⁸ provides a standardized system for implementing the NRP. NIMS provides a consistent yet flexible nationwide framework within which local, state, and federal levels of governments and the private sector can work effectively and efficiently to be aware of, prepare for, prevent, respond to, and recover from domestic incidents, regardless of their cause, size, or complexity. NIMS is mandated for use by all agencies in the executive branch of the federal government. Although not mandatory for use by the states and local jurisdictions, federal funding for disaster and homeland security initiatives is directly tied with these jurisdictions' use of the NIMS in preparation, planning, and response.

SUMMARY

Emergency management has evolved over the past 200 years. With the creation of DHS as an authoritative central executive agency for oversight of all federal emergency management activities, a level of cooperation and collaboration never before achieved is a possibility. At

the same time, refinements of and support for emergency management initiatives at the state and local levels offer the promise of better hierarchical integration during response and recovery.

Although some standards exist for emergency management, many more meaningful and measurable standards are needed. Education and training, although improved, still have not reached all levels of emergency management to the degree desired. Many communities still are short of critical supplies and resources, and certain problems, such as mass care issues and environmental recovery and surety operations, have not been resolved.

Nonetheless, great strides have been made, especially in the last few years, and have established a framework by which further improvements are indeed possible.

Local Disaster Response

Jerry L. Mothershead

All disasters are local. Regardless of type, magnitude, or progression, disasters affect communities; therefore, community responders will be the first on-scene and will remain for recovery operations well after supporting resources and organizations have departed.

Depending on the type of disaster, various government, public, and private organizations responsible for public safety, public security, and infrastructure maintenance will be tasked to save lives, preserve property, and identify and rebuild essential services for the population served. Prioritizing and coordinating these missions will require collaboration, cooperation, and understanding on the part of the leadership and membership of these response and recovery organizations.

In general, these services are organized in the United States within a jurisdictional framework, and overall coordination falls to the governing entities within these jurisdictions. Unfortunately, these government systems are not identically established throughout America. The general framework usually involves metropolitan areas (e.g., cities, towns) within a county, which is within a state organization. However, many “states” are in fact commonwealths, counties may be supplanted by parishes, and some states recognize townships or independent cities not subordinate to surrounding counties.

Thus, no single description of local response can be provided that is applicable to all localities. Rather, this chapter will address functional entities and notional organizational structures, processes, and responsibilities; concepts, rather than specifics, will be emphasized.

LOCAL GOVERNANCE

Protection, prevention, and response to emergencies and disasters are well-recognized government responsibilities. Depending on a number of factors, local jurisdictions either have systems in place for emergency response or band together with neighboring communities to provide overall emergency management to a large constituency. Certainly, jurisdictions with substantial populations tend to establish discrete offices, referred to herein as *emergency management offices*, to provide coordination for prevention, mitigation, planning, and response functions.

However, even in those discrete functional areas, there might be multiple government entities involved. Law enforcement is but one example. Cities usually have a discrete police department, with the chief of police reporting to the city governing entity (e.g., mayor, city council). However, if that city is within a recognized county, certain law enforcement responsibilities, even within city limits, may fall to the county sheriff’s office, and state police might be tasked with other or overlapping duties. The city might also harbor a local Federal Bureau of Investigation (FBI) office with federal law enforcement and investigatory responsibilities, and should that community include ports of ingress, other federal law enforcement entities, such as Customs and Border Protection, and U.S. Citizenship and Immigration Services, may have certain authorities within the jurisdiction.

Responsibilities become even more confusing when applied to public health and medical services. All states have a division or department of public health that usually falls within the executive branch of the state government. A public health infrastructure, which may contain regional, county, district, and city public health offices, may exist. Members of the public health organization are state employees. Medical care, on the other hand, may fall within the responsibilities of a variety of organizations. There are very few public health hospitals left in America, and most inpatient care is provided through private, for profit and not-for-profit, hospitals that do not limit their services to discrete jurisdictional boundaries. Physician offices and independent clinics outside of any one hospital’s organization are common in all communities. Increasingly, freestanding laboratories, other diagnostic centers, and other healthcare services also exist that are not part of larger healthcare systems, but they do form part of the healthcare network. Emergency medical services (EMS) (emergency ambulance services) may be provided by fire services, discrete government entities, hospitals, or contracted providers, and multiple EMS providers may support individual or multiple jurisdictions. EMS (and fire services) may be paid, career agencies, volunteer groups, or composites. Statewide, EMS may fall within the public health department, Emergency Management Agency, or another state organizational construct.

Under the paradigm of the National Response Plan (NRP), there are 15 essential functions that potentially

TABLE 12-1 COMMUNITY ESSENTIAL FUNCTIONS

FUNCTION	RESPONSIBLE ORGANIZATIONS
Transportation	Public works department
Communications	
Public works	Public works department
Firefighting	Fire and emergency services department
Emergency management	Local emergency management agency
Mass care	
Resource support	Various
Public health and medical	Jurisdiction's public health department
Urban search and rescue	Fire and emergency services department
Oil spills and hazardous materials	Fire and emergency services department
Agriculture and natural resources	
Energy	
Public safety and security	Jurisdiction's law enforcement organization
Recovery and mitigation	Various
External communications	Area emergency warning agency

NOTE: Blanks in the table indicate that the function is not typically a responsibility of a local jurisdictional office or entity or is not provided by government.

are required in the event of a disaster.¹ In the case of federal support, a discrete federal agency or organization has been identified as the primary coordinating entity for providing this functional support to state and local government. (Note that several states have additional, state-level essential functions.) These 15 essential functions, with the usual local entity responsible for their provision, are outlined in Table 12-1. What is most important is not the specific organization, since this may vary with the jurisdiction, but that, at the local level, some organization or entity has been assigned the principal coordinating responsibility and has the necessary resources (material, manpower, and economic) to provide for the reestablishment and maintenance of these services under emergency conditions or has the processes and framework to request, acquire, and incorporate outside resources into this functional organization.

Perusal of Table 12-1 will make it clear that not only are multiple, disparate local government agencies and organizations crucial to emergency management, but that participation may be necessary with nongovernment and industry organizations if the response is to be fully effective. Power, light, and natural gas resources and services are provided almost exclusively by private corporations. Crucial communications with the public will entail cooperation by local news media organizations and telecommunications corporations.

SUPPORTING ORGANIZATIONS AND CAPABILITIES

It is thus imperative that a full accounting of all local resources be considered during preparation and planning for emergency response. The most common forum in which this occurs is through Local Emergency Planning Committees (LEPCs). LEPCs and State Emergency

Response Commissions (SERCs) are mandated by the Emergency Planning and Community Right to Know Act.²

The act requires each state to set up an SERC.³ The 50 states and the U.S. territories and possessions have established these commissions. Indian tribes have the option to function as an independent SERC or as part of the state SERC in which the tribe is located.

In some states, the SERCs have been formed from existing organizations, such as state environmental, emergency management, transportation, or public health agencies. In others, they are new organizations with representatives from public agencies and departments and various private groups and associations. Duties of SERCs include:

- Establishing local emergency planning districts
- Coordinating activities of the LEPCs
- Reviewing local emergency response plans
- Monitoring legislation and information management concerning hazardous materials
- Maintaining situational awareness of locations of all major quantities of defined toxic industrial materials
- Establishing procedures for receiving and processing public requests for information collected under the Emergency Planning and Community Right to Know Act
- Taking civil action against facility owners or operators who fail to comply with reporting requirements

LEPCs normally include elected officials and representatives of law enforcement, civil defense, fire services, EMS, public health, local transportation agencies, communications and media organizations, facilities involved with the handling of toxic industrial materials, and the medical community.⁴ Others from the public at large may also be included. The primary responsibility of an LEPC is to plan, prepare for, and respond to chemical emergencies. LEPCs must identify and locate all hazardous materials; develop procedures for immediate response to a chemical accident; establish ways to notify the public about actions they must take; coordinate with corporations and plants that harbor toxic industrial materials; and schedule and test response plans. An LEPC also receives emergency releases and hazardous chemical inventory information submitted by local facilities and must make this information available to the public. An LEPC serves as a focal point in the community for information and discussions about hazardous substances, emergency planning, and health and environmental risks.

LOCAL RESOURCES

One of the many goals of the Metropolitan Medical Response System (MMRS) Program is to try to coalesce all potential response capabilities into collaborative functional areas.⁵ In the case of health and medical support, this extends far beyond the traditional boundaries of EMS, hospital-based care, and local jurisdiction public health. Under the MMRS paradigm, one or multiple jurisdictions should join together to optimize the use of

resources along a more regional approach, to the benefit of all. The ability of all functional elements of response to surge capabilities and capacity in reaction to an emergency cannot be overemphasized. Failure of complementary surge in even one sector can result in bottlenecks and lack of optimal response across the spectrum.⁶

In addition to traditional entities and organizations, there is a wealth of additional resources that could be brought to bear in the event of a public health emergency or other disaster with significant health effects. These range from private organizations, corporations, and other business ventures through the recruitment of appropriate volunteers, either from volunteer organizations or the public at large. A partial listing of these other medical or paramedical resources is included in Table 12-2. What is important in local planning is the recruiting, training, and cataloging of all potential participatory organizations, entities, and individuals; cooperative planning on best use of these resources; and training of these individuals and organizations to produce a cohesive response organization. Convergent volunteerism is an important adjunct to area emergency managers, but planning for utilization of these resources is a necessity for optimal use.⁷

One organization of particular note is the National Voluntary Organizations Active in Disaster (NVOAD).⁸ NVOAD coordinates efforts by many organizations responding to disaster. These organizations provide more effective service with less duplication by getting together before disasters strike. This cooperative effort has proven to be the most effective way for a wide variety of volunteers and organizations to work together in a disaster.

An initiative recently sponsored by the U.S. Department of Health and Human Services (DHHS), through the Office of the Surgeon General, is the Medical Reserve Corps (MRC).⁹ The mission of the MRC is to establish teams of local volunteer medical and public health professionals who can contribute their skills and expertise throughout the year as well as during times

of crisis. The MRC program office functions as a clearinghouse for community information and “best practices.”

MRC units are made of locally based medical and public health volunteers who can assist their communities during emergencies, such as an influenza epidemic, a chemical spill, or an act of terrorism. MRC units are community-based and function as a specialized component of Citizen Corps, a national network of volunteers dedicated to making sure their families, homes, and communities are safe from terrorism, crime, and disasters of all kinds. Citizen Corps, AmeriCorps, Senior Corps, and the Peace Corps are all part of the USA Freedom Corps, which promotes volunteerism and service throughout the United States.

LOCAL RESPONSE CONCEPTS OF OPERATIONS

Since no two disasters are identical, the actual concepts of operations during response will vary depending on the actual circumstances. There are, however, some basic concepts that will affect operations that should be well appreciated by emergency managers and planners.

Community Warning

The ability of the community to be prepared for the disaster is predicated on adequate forewarning of the impending event. Unfortunately, many disasters do not lend themselves to early detection by any form of sensor, or analysis has not reached the point that actions may be appropriately taken. It is well documented in the literature that “false” warnings actually impede future community actions, a classic example of “the boy crying wolf” once too often.

Most warnings are issued by government agencies. Most dissemination and distribution systems are owned and operated by private companies, and effective public-private partnerships are required. Great strides are taking place in threat detection and warning communications technology. Warnings are becoming much more useful to society as lead time and reliability are improved.

To be effective, warnings should reach, in a timely fashion, every person at risk and *only* persons at risk, no matter what they are doing or where they are located. There is a window of opportunity to capture peoples’ attention and encourage appropriate action. Appropriate response to warning is most likely to occur when people have been educated about the hazard and have developed a plan of action well before the warning. Warnings must be issued in ways that are understood by the many different people within our diverse society. A single, consistent, easily understood terminology should be used, which may need to be conveyed multilingually in certain communities. If warnings that are not followed by the anticipated event are inconvenient, people are likely to disable the warning device.

Examples of failed or ineffective warnings include:

TABLE 12-2 SOURCES OF MEDICAL RESOURCES IN A COMMUNITY

EMS/Transportation	Outpatient Facilities
Ambulance companies	Physician offices
Hospital ambulances	Physical therapy centers
Military field ambulances	Urgent care clinics
Air ambulance services	Dental offices
School buses	
Transit services	Logistics
Taxi services	Pharmacies
	Medical supply centers
Diagnostic Services	Department stores
Freestanding laboratories	Furniture stores
Diagnostic centers	
Dialysis units	Allied Health Personnel
	Veterinarians
Inpatient Facilities	Medical students
Nursing homes	Nursing students
Rehabilitation centers	Allied health training centers
Addiction treatment centers	Medical explorer units
Hotels	School/occupational health nurses
Gymnasiums	

- Alabama, March 27, 1994: A tornado killed 20 worshippers at a church service. A warning had been issued 12 minutes before the tornado struck the church. Although it was broadcast over the electronic media, the warning was not received by anyone in or near the church.
- Florida, Feb. 22-23, 1998: Tornadoes killed 42. The National Weather Service issued 14 tornado warnings. The warnings were not widely received because people were asleep.

A variety of warning devices needs to be used to reach people according to the activity in which they are engaged. Effective warning systems should also have redundancy. On May 31, 1998, a tornado in South Dakota killed six. Sirens failed because the storm had knocked out power.

Response Scene Operations

The immediate concern of response organizations is the preservation of life. This not only includes actions directed at victims of the disaster—search and rescue, extrication, triage, scene treatment, transportation, and definitive treatment and rehabilitation—but also at preventing further risks to the community through containment of the disaster.

The disaster *must* be contained. This is relatively easy to envision in the case of a spreading hazardous materials incident, but the concept applies to *any* disaster. Containment can be both geographic (erecting levees for flood protection) or can be internal to the disaster area; for example, frequent sequelae of certain disasters are rioting and looting or vandalism. These types of actions actually represent secondary or compound disasters. In the case of a progressive infectious disease outbreak (e.g., one caused by a contagious agent—measles, influenza, or smallpox), containment of disease spread is the principal goal of public health. Failure to contain the disaster early on will result in significantly greater losses, whether economic or lives.

All the actions one would think of to rescue and treat individuals directly affected by the disaster must take priority over salvage and property protection operations. Sequentially, these actions include:

- **Search and rescue:** In a hazardous materials (HazMat) environment, up to an hour may pass before HazMat teams even enter the “hot zone.” Thus, those minimally injured may self-extract and seek treatment well before those most severely injured, resulting in a bimodal presentation to area hospitals.
- **Triage of victims:** This may have to be done at multiple stages of the operations. Classic triage is based on trauma, and this form of triage may not be the best for victims of chemical or biological incidents.
- **Decontamination, especially in known HazMat incidents:** A study¹⁰ conducted several years ago revealed that only 18% of victims of HazMat incidents who were treated at hospitals underwent decontamination before arrival. In the 1995 sarin attack in

Tokyo, nearly 600 patients arrived at St. Luke’s Hospital within the first 45 minutes of the incident. None had been decontaminated (fortunately most did not require this). Still, a number of hospital personnel developed nerve agent exposure symptoms from treating and evaluating the victims.

- **On-scene treatment of victims:** The majority of injured victims do not stay at the scene long enough to receive prehospital triage and treatment. Those who remain on the scene are usually the most severely injured and are unable to escape the scene before the arrival of rescue assets. Also of interest, however, is that several studies have recently called into question the efficacy of victims waiting for responders.¹¹ In one study, the morbidity and mortality of those who waited for EMS agencies was significantly higher than for those who were transported to community hospitals by the most expeditious method available.
- **Transportation of victims:** This is also more complicated in a disaster situation. Although the nearest hospital might be the best equipped, if it has already been overwhelmed by the arrival of other critically ill victims, EMS will need to invoke “first wave” protocols.¹² This occurs when the most critically ill patients are distributed among potential receiving hospitals with little regard of proximity.
- **Re-triage of victims and receiving fixed-site medical treatment facilities:** Procedures and policies must be in place to handle this sudden surge of victims while still tending to already anticipated patients not involved in the mass casualty incident.

First responders will be overwhelmed in a true mass casualty incident. Most first responders and EMS personnel have been trained in the simple triage and rapid treatment (START) algorithm.¹³ This algorithm, which assesses mental status, respiratory effort, and peripheral perfusion, can be performed in as little as 30 seconds and allows only minimal treatment—reposition of the head to decrease airway resistance and bandaging of gross hemorrhage.

Ambulance and vehicle control at the scene are important considerations. In the Avianca plane crash on Long Island in 1979, so many rescue vehicles arrived unsolicited that departing vehicles could not get on the one-lane road that provided the sole ground access to the scene. All arriving vehicles should be sent to staging areas out of the way, with at least one staff member remaining with the vehicle at all times.

Contaminated vehicles pose a risk to both patients and staff as a result of residual contamination or from off-gassing from patients in the confined treatment compartment. In general, patients whose conditions are stable should undergo full decontamination at the scene before transportation. Patients whose conditions are unstable may undergo gross decontamination, which may entail removal of clothing only, and be placed in nonporous patient wraps for transport. Once a vehicle is used for a potentially contaminated patient, it should be considered contaminated until fully cleaned inside and out.

Receiving Facility Considerations

Receiving facilities must have capabilities to decontaminate potential patients and should have sufficient space to maintain these patients for a period, even if the patients are to be eventually transferred elsewhere.

First-wave protocols should be developed in communities with multiple hospitals. A first-wave protocol matches hospital resources with total victim requirements. It does a victim little good to be taken to a facility already overrun with critical patients merely because it is the nearest hospital, while other facilities that are slightly farther away remain empty. Distribution of victims throughout the entire hospital “system” will do the most good for the most number of patients, and this may be considered a form of transportation triage.

During planning, treatment facilities must determine how to rapidly expand their services for a surge of patients. This entails increasing staff through recall, expedient credentialing of volunteers, canceling elective procedures, and premature discharge of patients whose conditions are stable. It also means that additional bed space be made available by using, for example, cots, litters, cafeterias, other open spaces, and same day surgery clinics. Although historically few hospitals have suffered supply shortages in disasters in the United States, some caches should be available to handle the disaster until outside resources arrive.

Above all, facilities must be protected. If a facility becomes contaminated, it threatens this entire function. Facilities should have methods for expedient collective protection and must have security personnel available for access control.

Public Welfare Issues

In a disaster that involves large geographic areas, people will be displaced. Depending on the location, the socioeconomic status of the community, the type of disaster, and adequacy of the warning (that was heeded by the population), this may or may not be a problem.

- **Shelter:** The majority of evacuees on the East Coast as the result of hurricane warnings generally travel inland and stay with friends or relatives over a larger geographic area where the impact of this surge population is not felt as greatly. Still, those who have not evacuated, or those without family support, may be forced into shelters.
- **Healthcare:** It must be remembered that a displaced population has additional needs due to the recent stressors, but individuals within this cohort may also have special needs in and of themselves—especially if residents of nursing homes or rehabilitation centers or significant numbers of chronically ill patients are part of the displaced population.
- **Family assistance programs:** These programs become important very early in a disaster. People from outside the region want to know that their loved ones are safe. Families get separated during the disaster, and relocation is an important issue. Bereavement

programs for survivors must be ready to implement during this period.

ISSUES IN LOCAL RESPONSE

There are a number of cross-cutting issues or functions that affect all phases of emergency response. These include:

- The establishment and manning of emergency operations centers and command posts.
- Effective unified or incident command systems operations.
- Intra-agency and interagency communications.
- Effective resource management, both material resources and manpower.
- The ability of different sectors of the response to rapidly and seamlessly integrate with outside agencies, whether locally through memoranda of understanding or through activation of state or federal emergency response plans.
- The media, who will arrive almost immediately and demand information (effective media relations will pay off during after-action reviews; at the same time, the public will want information and may need both information and direction).
- In the event of a disaster caused by criminal or terrorist acts, forensic issues will be important as crime scene investigators and consequence management agencies work together.
- Legal issues are always present, ranging from the application of Occupational Safety and Health Administration standards to liability issues.
- Finally, depending on the particular disaster and the community’s response to it, there may be issues of crowd control, vandalism protection, and other law enforcement agency functions beyond crime scene investigation.

SUMMARY

Local response to disasters is where the rubber meets the road. Effective planning, preparation, and response entail identification and cataloging of all available resources, education and training of personnel from disparate organizations, and a response structure that allows seamless integration of these assets.

Disaster Planning: State Programs and Response

Esther H. Chen, Bruce Y. Lee, and Jerry L. Mothershead

State disaster management has changed dramatically in the past 15 years. State administrations have emerged from the shadow of the federal government to develop their own disaster response systems and become the umbrella agencies that protect their citizens from disasters. Because the state can exercise its authority over community disaster control programs and can mobilize federal resources, it has become a focal point in disaster planning and relief. After the attacks on the World Trade Center and the Pentagon on Sept. 11, 2001, preparedness against terrorism became another important focus of state governments. Nonetheless, comprehensive, all-hazards emergency management continues to be the principal goal of state emergency response agencies. This chapter discusses a typical state's emergency management organization, reviews pertinent state laws, and highlights a few specific policy changes of the post-Sept. 11 era.

HISTORICAL PERSPECTIVE

Before World War II, most states did not have well-organized disaster response organizations or systems and relied primarily on fragmented federal programs for postdisaster assistance. Between World War II and the 1970s, the establishment of several federal agencies, such as the Communicable Disease Center (forerunner to the Centers for Disease Control and Prevention) in 1946 and the Department of Health, Education, and Welfare in 1953; the passage of federal laws to deal with civil unrest in the 1960s; and airplane hijackings in the 1970s improved communications among the different states and encouraged slightly more uniformity among state disaster programs.¹ In 1974, the National Emergency Management Association was formed to share common state experiences in dealing with natural disasters and provide interstate assistance.² However, disaster management remained fragmented until 1979, when President Carter established the Federal Emergency Management Agency (FEMA) to consolidate federal response and coordinate local, state, and national disaster preparedness and mitigation efforts.³⁻⁵ In 1986, the Emergency Planning and Community Right to Know Act (EPCRA) mandated

states to develop their own emergency management agencies (EMAs) or commissions to plan for and respond to state and local disasters.^{6,7} State and community governments now share the responsibility of protecting the citizens within their own jurisdictions. Currently, all 50 states and U.S. territories have EMAs, and 23 states have followed the federal lead and have established state departments of Homeland Security.⁷⁻⁹

CURRENT PRACTICE

Emergency Management Infrastructure

Emergency Management Agency

A state's EMA is responsible for coordinating state disaster response, supporting county and local governments in pre-disaster planning and postdisaster relief, and accessing external aid. A typical EMA consists of several state and local agencies and is headed by a director who reports to the state governor (Table 13-1). The governor is the chief constitutional officer authorized to declare a "state of emergency," mobilize state and local agencies to provide assistance, and temporarily suspend statutes or orders that would obstruct actions during a state disaster. Some states have more disaster-related resources, and many have established extensive emergency management commissions.¹⁰

The EMA is also responsible for the state's Emergency Operations Plan (EOP), which facilitates timely and algorithmic response to specific disasters.¹¹ A state's EOP typically has three major components: a tactical plan assigning specific response tasks, an action plan to deploy resources, and a long-range needs and resources plan.

Elements of emergency preparedness common to all states' emergency management programs include:

1. **Communications:** This includes response personnel notification and maintaining and testing statewide communications architectures.
2. **Hazard awareness:** Information about natural disasters is provided to educate the public on safety and simple prevention measures. Some states also publish information on hazard mitigation.^{5,12}

TABLE 13-1 EMERGENCY MANAGEMENT COUNCIL

PARTICIPANT	DESCRIPTION
Governor	Chief executive officer: Declares disaster emergencies, directs all state and local agencies to provide assistance, and temporarily suspends any statute or order that would delay action during a state disaster emergency
Director	Coordinates the state's disaster management activities in coordination with the directors of other state agencies
State Agency Officials	Adjutant general Commissioner, State Police Attorney general State fire commissioner Director, Emergency Services Agency Secretary of Health Secretary of Environmental Protection Secretary of Transportation Secretary of Agriculture Secretary of Public Welfare Secretary of Labor and Industry

- Disaster preparedness:** A two-tiered approach to community preparedness is used. At the local level, state funds are provided to establish temporary shelters, develop appropriate disposal for hazardous materials, and organize emergency response protocols. Information is provided to the general public on evacuation procedures, disaster supply kits, and family emergency planning. Several states have even developed resources for children.^{13,14}
- Training and exercises:** Professional development for emergency response and administrative personnel and technical training are provided, often in conjunction with courses developed by FEMA.^{11,12} At the community level, disaster drills and exercises are also offered.
- Threat alerts:** The EMA provides daily advisories and warnings on natural and technological threats. More specific information on potential disasters is provided to emergency managers.
- Emergency resources:** The EMA maintains a current compendium of available emergency management resources.
- Regional planning:** Local and community governments have their own EOPs and can use state resources to disseminate public safety information, schedule training exercises, and periodically assess the hazard risks of their community.

A representative from the state EMA is normally the chief operations officer for the state Emergency Operations Center and is responsible for coordinating all state responses in the event of actual statewide disasters.

State Emergency Response Commission

Mandated by the EPCRA, the State Emergency Response Commission (SERC) consists of the EMA

director, directors of state agencies (e.g., Department of Health, Department of Transportation, Department of Food and Agriculture), and representatives of Local Emergency Planning Committees (LEPCs). SERC responsibilities include establishing and supervising LEPCs, providing the public with hazardous materials information, and reviewing state and local emergency response plans.

Department of Homeland Security

Since the development of the federal Department of Homeland Security (DHS), 23 states have separated state homeland security from the jurisdiction of the EMA. The state DHS director reports directly to the governor; coordinates state and local resources devoted to terrorism detection, prevention, response, and recovery; and has full authority to use all available state and local agencies for public safety. Other state programs include:

- State security plan:** All states have security plans that provide the framework to enhance their ability to protect their citizens from terrorism. This includes a counterterrorism system, distributing funds to local and state agencies dedicated to public safety, and a tactical response strategy.
- Security grant funding:** States can distribute federal funds to enhance all programs dedicated to terrorism preparedness and training.
- Citizen preparedness:** Information is provided to the public about preparing for a potential terrorist act and to educate citizens about potential chemical, biological and radiological exposures.
- Training:** Training programs are offered on community and state levels. Emergency medical teams are trained to recognize biological, chemical, and radiological exposures and respond to mass casualty events.

Keeping state EMAs and DHSs separate has its advantages. Two separate, smaller, leaner organizations can focus on their respective areas and build the necessary expertise more efficiently than a single large organization burdened by a wider variety of responsibilities. Having two separate but similar organizations also means that backup resources are available should one organization be unable to fulfill its duties. Separate organizations with different organizational cultures and personnel can also offer different perspectives on the same problem.

Conversely, there are disadvantages. Two different organizations may mean redundant services and personnel, significantly increasing costs. Also, communication, which is crucial to any emergency management infrastructure,¹⁵ may be hindered by bureaucratic and administrative barriers separating the two. Moreover, it is not always clear which problems fall under whose jurisdiction, especially when it cannot readily be determined whether bioterrorism, natural disasters, or both are responsible. Additionally, differing protocols and philosophies can cause conflict and confusion.

National Guard

The state National Guard, supervised by the Adjutant General and composed of both the Air National Guard and the Army National Guard, was established in colonial times to protect citizens during war and to provide assistance during emergencies. It has dual state and federal responsibilities.¹⁶ Its mission under state law is to protect life, restore property, and preserve peace and public safety. When not under federal control, Guard personnel may be deployed by the governor for emergency management.^{17,18} The National Guard offers additional personnel, federal training, and federal resources. However, relying on the National Guard has its potential perils. The National Guard's other responsibilities, especially during wartime, may limit its availability. Even when Guard personnel are available, it takes time for them to assemble and respond. Moreover, during peaceful times, the state may have little experience working with the National Guard, which may prevent the state from efficiently using it when crises arise. Guard personnel would have to work with unfamiliar state and local personnel and resources. Additionally, competing responsibilities and a shortage of career advancement opportunities may be hindering the National Guard's ability to recruit and retain adequately specialized personnel.¹⁹

Department of Health

Each state has a Department of Health (DOH) whose mission includes providing public health surveillance and response to a medical incident or public health threat. The DOH usually has jurisdiction over the following state agencies and programs:

1. **Emergency medical services (EMS):** Local EMS systems provide first responders to disasters. Funding is provided toward responder training, equipping vehicles for catastrophic casualty events, and coordinating regional and interstate EMS systems when local resources are overwhelmed.
2. **Community health districts:** Programs supported include reporting and detecting communicable diseases, providing immunizations, and promoting public and environmental health in the community. Health center personnel are educated on recognizing and containing bioterrorism agents and diseases.
3. **Public health surveillance:** The DOH is responsible for public health disease surveillance (including those due to bioterrorism) and interfacing with appropriate federal agencies.
4. **Environmental health epidemiology:** Responsibilities include surveillance of environmental toxins and chemical and physical agents as well as biomonitoring.
5. **Hospital organizations:** During an emergency, the DOH has the authority to mobilize medical personnel and acquire pharmaceutical and medical supplies from hospitals. It also provides coordination between emergency management and medical organizations.
6. **Strategic National Stockpile:** The state DOH is responsible for oversight and coordination of public mass prophylaxis and vaccination campaigns in the event of a bioterrorist attack or other public health emergency.

EMS Agency

The state EMS agency oversees the statewide EMS system to ensure timely and appropriate prehospital care. It is also responsible for managing the state's emergency prehospital response to disasters and for providing funds to support disaster preparedness. This agency has several specific roles and responsibilities:

1. **EMS systems development:** The agency is responsible for assessing and improving the multiple regional and local EMS systems based on community needs, providing resources for developing new EMS systems, developing standards for EMS systems statewide, and reviewing local EMS plans.
2. **Trauma systems development:** The agency sets state trauma systems standards. It also evaluates trauma systems in accordance with changing needs of the community, designates trauma centers, and reviews the major trauma registry for continuous quality improvement.
3. **Education and training:** Standards for all aspects of out-of-hospital care systems are established by the state agency. The state agency also reviews the course curricula for regional EMS providers, develops a statewide EMS communications plan, and sets the standards for first aid training programs.
4. **Disaster preparedness and response:** A state's EMS agency is responsible for developing or assisting local health agencies in the establishment of emergency response plans, forming and coordinating a statewide mutual aid system, and testing these protocols through drills and exercises.
5. **Public education and information:** Information about the EMS system is distributed to promote public awareness of its role in the community.

State Hospital Organizations

Hospitals, health systems, and continuing care providers in each state have formed a collective association with the purpose to improve the healthcare delivery in their communities, provide access to healthcare for their citizens, and improve laws and regulations. The organization represents its members to state and federal governments and national organizations on issues of public health policy, promotes professional development for healthcare personnel and leaders, and facilitates communication among its members. Furthermore, it coordinates disaster preparedness in the hospitals and develops guidelines, including those pertinent to disaster preparedness.

State Legislation

Disaster Response

Numerous federal and state statutes, executive directives, and regulations that address terrorism, homeland security, and consequence management have been enacted since 2001, but the first comprehensive approach to federal disaster assistance was enacted in

1974 with the passage of the Robert T. Stafford Disaster Relief and Emergency Assistance Act.²⁰ One operational component of the Stafford Act is the Federal Response Plan,^{21,22} which, in December 2004, evolved into the National Response Plan.²³ Federal resources that may be deployed include damage assessment, medical personnel and equipment, and emergency communications. The Stafford Act and the EPCRA form the backbone of federal policy on disaster assistance and are discussed in other chapters of this textbook.

Around the time the EPCRA was passed, each state also passed its own Emergency Services Act, which confers emergency powers to the governor, assigns functions to state agencies during emergencies, and authorizes the mobilization of all local and state resources toward disaster management. Through this and other legislation, the governor is usually authorized to create or suspend any statute during a state emergency, procure all state and local resources needed during a disaster, mobilize the National Guard and private personnel if necessary, and use news wire services if other communication methods are unavailable.

Since most states lack the resources to respond to a major catastrophe on their own, Congress passed the Emergency Management Assistance Compact (EMAC) in 1996 to enable states to assist each other during any disaster.²⁴ Any EMAC state can request personnel (including from the National Guard) and material resources from another state for any emergency. The requesting state is responsible for the legal liability of all out-of-state personnel and costs incurred. Any EMAC state can refuse another state's request. As of May 2005, 48 states (excluding California and Hawaii) had signed this agreement.

Public Health Emergency Response

Federal legislation delineates federal and state public health responsibilities. The U.S. Department of Health and Human Services (DHHS) is responsible for controlling contagious diseases threatening U.S. borders, conducting disease surveillance and biomedical research, and providing medical assistance during disasters. After 2001, following the lead of the DHHS, most states established Public Health Agency offices that are specifically responsible for public health emergency preparedness and response programs. Under the Public Health Services Act, state and local DOHs may be requested to assist in the quarantine of communicable diseases, are required to train their personnel for health-related activities, and can request temporary aid from the DHHS during health emergencies.²⁵

Although most states had existing public health and disaster-related laws and regulations sufficient to cover most exigencies, after the anthrax incidents in the fall of 2001, a systematic review of those codes was conducted, deficiencies were identified, and the Model State Emergency Health Powers Act (MSEHP) was prepared for the Centers for Disease Control and Prevention.^{26,27}

A "model act" is one that states look to as they consider their own legislation. Many states have incorporated many of the MSEHP provisions into law. The MSEHP is designed to facilitate the early detection of and response to a health emergency, and, among other requirements, grants extraordinary powers to an adoptive state executive branch in the event of a defined public health emergency.

Comprehensive State Disaster Response

Idaho's response to potential anthrax exposures in October 2001 illustrates how local, state, and federal resources may be coordinated during a major disaster. The crisis began when Idaho's Emergency Medical Services Communication Center received an exponential increase in the number of calls for suspicious powdery substances and other hazardous materials. The majority of these calls were from local law enforcement officers, who serve as on-scene commanders during hazardous materials investigations. The communications center then informed, per protocol, the governor, EMA director, and state public health, law enforcement, and hazardous materials officials at the state EMA to determine the best management strategy. Those officials alerted the state laboratory representatives that they would be receiving samples for testing, distributed public health guidelines for healthcare providers to district health departments and hospitals, and contacted the Federal Bureau of Investigation to deal with the few associated mail threats. The Centers for Disease Control and Prevention provided protocols for 11 additional laboratories whose personnel had to be trained in test procedures because the state laboratory staff was quickly overwhelmed.²⁸ If in-state resources were inadequate to handle the disaster, such as after the events of Sept. 11, the governor could have elicited the aid of laboratories, healthcare providers, and law enforcement or military personnel from neighboring states.

SUMMARY

States play a key role in coordinating local and federal responses to natural and manmade disasters. Many states, by themselves, lack the resources to cope with large-scale disasters and therefore must enlist the aid of other states through the EMAC or federal government. The events of Sept. 11, 2001, have prompted significant improvement in states' ability to handle terrorist attacks, and as a consequence, state government agencies are now better able to respond to all potential disasters. Future directions to optimize emergency management include establishing standards for disaster management and planning on state and local levels, enhancing communications between emergency responders, improving threat detection and identification through technological advances, and modifying existing emergency response capabilities to meet the challenges of emerging threats.

Selected Federal Disaster Response Agencies and Capabilities

Jerry L. Mothershead, Kevin Yeskey, and Peter Brewster

Chapter 11 provides a historical accounting of the evolution of emergency management in America and the basic framework for current concepts of operations. This chapter discusses selected federal response organizations and agencies, supporting programs for state and local emergency managers, and response capabilities. With the near-exponential growth in disaster management capabilities and initiatives that has occurred since the terrorist attacks of 2001, it would be impossible to discuss all of the many federal capabilities to any significant degree. Thus, this chapter focuses on the agencies of principal interest to public health, medical emergency managers, and healthcare professionals.

A more detailed presentation of current concepts of federal operations is provided as well as a discussion of some of the more significant issues and challenges facing the federal sector in responding to disasters or catastrophic emergencies of any type.

PRINCIPAL FEDERAL AGENCIES

Although virtually all of the federal executive branch agencies have capabilities and expertise that could be brought to bear in a disaster to save lives, reduce pain and suffering, and otherwise mitigate the impact of these events on the human condition, five stand out as supporting programs that provide the most direct support in this endeavor:

- U.S. Department of Homeland Security (DHS)
- U.S. Health and Human Services (DHHS)
- U.S. Department of Defense (DoD)
- Department of Veteran's Affairs (DVA)
- American Red Cross (ARC)

Department of Homeland Security

The organizational structure and overarching functions of DHS are described in Chapter 11. Among the many provisions of the Homeland Security Act of 2002, three important programs were transferred from DHHS to DHS: the National Disaster Medical System (NDMS), the Strategic

National Stockpile (SNS) program, and the Metropolitan Medical Response System (MMRS).¹ Additionally, although it maintained many of its autonomous functions, the Federal Emergency Management Agency (FEMA) was transferred into the Emergency Preparedness and Response Directorate of DHS in 2003.

National Disaster Medical System

NDMS is a public/private partnership between DHS/FEMA, DHHS, DoD, DVA, and civilian hospitals and health professionals. NDMS serves two primary functions: it is a backup to military healthcare operations in the event of overwhelming combat casualties, and it provides federal healthcare support to casualties resulting from disasters in the United States and its territories.² Originally established by memorandum of understanding in 1984, NDMS was codified into law in 2002. There are three components to NDMS: (1) on-site healthcare operations, (2) medical evacuation, (3) and definitive care. NDMS may be activated as the result of a presidential declaration of a national emergency. It may also be activated at the direction of the secretaries of DHS, DHHS, or DoD.

On-site healthcare operations are provided principally through the mobilization of disaster medical assistance teams, or DMATs. There are 85 teams, of which approximately 24 are considered operational at any given time. The number and capability of DMATs are evolving continually as new teams are being formed and established teams are augmenting their capabilities. Most teams are composed of more than 100 physicians, nurses, and allied healthcare personnel who are sworn in as temporary federal employees and who volunteer their time to prepare and train for emergency operations. In the event of activation, they become federal assets, with attendant liability protection. The majority of DMATs provide general clinical operations in disaster areas, either on-scene or as augmentation staff to local hospitals. A number of specialty teams exist, including burn, pediatric, crush injury, and mental health teams. Four disaster veterinary assistance teams (DVATs) and 10 disaster mortuary operations response teams (DMORTs) are also components of NDMS. One DMORT is specially

trained in the handling of contaminated or contagious remains. There are also three larger national medical response teams/weapons of mass destruction teams (NRMT) located in North Carolina, Colorado, and California. These teams are specially equipped and trained to assist local emergency response organizations in the event of terrorist events involving chemical, biological, or radiological substances. Finally, a newly developed Family Assistance Core Group has been incorporated into NDMS. When deployed, DMATs are self-sustaining for three days and are supported by management support units (MSUs) for resupply.

Medical evacuation operations are coordinated by the DoD.³ Medical regulation is managed by the Global Patient Movement Requirements Center (GPMRC) at Scott Air Force Base, Ill. This is the same system used to evacuate military casualties in peacetime or during combat operations worldwide. Actual medical evacuation occurs primarily through the use of fixed-wing U.S. Air Force assets, such as the C-141 Starlifter and the C-17 Globemaster III (each of which can accommodate in excess of 50 litter patients), under the auspices of the commander of the U.S. Transportation Command. Nontraditional air evacuation platforms or ground conveyances can also be used, as required. Most DMAT members have training in basic fixed-wing and helicopter operations as they pertain to the evacuation of patients.

Definitive care is provided by the 1800 hospitals that have voluntarily agreed to support NDMS operations. In all, approximately 100,000 beds (including the staff to support them) could be made available throughout the United States. Cooperating hospitals are coordinated through regional federal coordinating centers (FCCs), which are managed by the VHA or the military services hospitals.⁴

Strategic National Stockpile (SNS)

The SNS, originally authorized by Congress in 1998, has as its goal the rapid mobilization and provision of pharmaceuticals and other medical supplies to areas affected by public health emergencies or disasters of any cause. The SNS program has a number of elements, including scientific review, education, training, and technical and logistical support. The primary material components of the SNS are the 12-hour push packages and vendor managed inventory (VMI) supplies.⁵

Twelve push packages, preconfigured and under environmental and security safeguards, are strategically placed throughout the United States and can be deployed to arrive at the nearest suitable airfield to a disaster within 12 hours of release by either the secretary of DHS or DHHS. Push packages are large caches, requiring more than 5000 square feet of storage space, that may be transported by air or ground conveyance. Supplies include antibiotics, antiviral agents, and airway and intravenous supplies. Ventilators, stored separately, may be shipped as needed. Vaccines, also stored separately, may be shipped with or without the entire cache. In 2003, regionally placed chemical agent antidotes were established under the CHEMPACK program to provide for more timely arrival.

If specific supplies are known to be needed in advance of push package shipment, these may be obtained through VMI stocks, which are maintained by pharmaceutical or medical supply corporations that have contracts with the federal government. VMIs were designed, however, to be follow-on packages of specifically needed supplies to arrive 24 to 36 hours after the push packages.

All states are required to develop and exercise plans for the request, acquisition, storage, staging, distribution, and dispensing of SNS caches to prophylaxis or vaccination centers or area hospitals. Caches will be accompanied by a small team of medical logisticians referred to as technical assistance response units (TARUs).

Metropolitan Medical Response System.

In 1997, DHHS established the Metropolitan Medical Strike Teams (now the Metropolitan Medical Response System [MMRS]) to integrate the various, disparate response functions. Although designed principally to enhance preparedness for chemical or biological terrorist attacks, MMRS can be used effectively in all types of disasters. The MMRS program provides technical assistance and funding to large metropolitan areas to establish enhanced capabilities within existing systems. Grants are linked to compliance with a series of specific measurable objectives. Originally designed to focus on the largest 120 communities in the United States, the program has been expanded with the goal of establishing MMRS presence in 200 metropolitan areas.⁶

Department of Health and Human Services

DHHS is the federal agency that has the responsibility of protecting the health of the nation and providing essential services to all U.S. citizens. DHHS has an annual budget of \$502 billion (2003 fiscal year) and employs more than 65,000 personnel.⁷ DHHS administers more than 300 programs in 11 operating divisions and is the parent organization for the Commissioned Corps (CC) of the U.S. Public Health Service (USPHS).

DHHS has a long history of providing disaster response and preparedness activities domestically and internationally.⁸ DHHS is the lead federal agency for coordinating the federal health and medical response services (Emergency Support Function #8), as described in the National Response Plan (NRP) (Box 14-1).⁹ DHHS is a partner in the NDMS. The Public Health Threats and Emergencies Act of 2002 authorizes the DHHS secretary to take appropriate actions if a public health emergency is determined to exist and to establish a Public Health Emergency Fund.¹⁰ Other statutes authorize the U.S. Surgeon General to make and enforce regulations to "prevent the introduction, transmission, or spread of communicable diseases from foreign countries into States or possessions, or from one State or possession into any other State of possession."¹¹

DHHS disaster response and preparedness activities are conducted in the Operating Divisions and the USPHS CC.

BOX 14-1 EMERGENCY SUPPORT FUNCTION #8: PUBLIC HEALTH AND MEDICAL SERVICES

1. Assessment of health/medical needs
2. Surveillance of healthcare issues
3. Acquisition and distribution of medical care personnel
4. Acquisition and distribution of health/medical equipment and supplies
5. Patient evacuation
6. In-hospital care
7. Food/drug/medical device safety
8. Worker health/safety
9. Radiological monitoring
10. Chemical monitoring
11. Biological monitoring
12. Mental health assessment
13. Development and dissemination of public health information
14. Vector control
15. Water safety; wastewater and solid waste disposal
16. Victim identification/mortuary services

Coordination is performed at the assistant secretary level within DHHS. DHHS also convenes the National Science Advisory Board for Biosecurity, which guides the development of systems for biosecurity research peer review, guidelines for identification and conduct of research that might require security surveillance, professional code of conduct for scientists and laboratory workers, and materials to educate the research community about biosecurity.

Office of the Assistant Secretary for Public Health Emergency Preparedness (ASPHEP)

This office provides (1) interface between agencies within DHHS and other federal departments, agencies, and offices and (2) interface between DHHS and state and local entities responsible for public health and emergency preparedness. The ASPHEP ensures that health and medical vulnerabilities are identified and prioritized within the DHHS; that DHHS preparedness programs are coordinated and integrated with other federal programs; and that response activities are coordinated within DHHS and integrated with other federal, state, and local response.¹² ASPHEP manages a state-of-the-art command center for the DHHS secretary. This facility serves as the information management and communications hub for DHHS agencies and is the primary point of contact for other federal agencies. The command center is staffed around the clock, daily. The office also maintains a scientific group that oversees the development and procurement of all SNS medical countermeasures.

ASPHEP works with state and local officials to enhance health and medical preparedness and coordinates various federally funded preparedness activities. DHHS has established guidelines, benchmarks, and competencies to serve as markers of preparedness.

APSHEP has personnel who are deployed to the field during responses. The team, known as the Secretary's Emergency Response Team (SERT), deploys to the DHHS regional office (although they can deploy to more forward

positions) and serves as an advisory team to the secretary, through the ASPHEP. DHHS uses its regional offices and regional health administrators as the primary response coordinators of field operations. SERT members and regional response personnel can also serve as Emergency Support Function #8 liaisons at the state operations center, DHS disaster field office, or DHS regional office.

Agency for Healthcare Research and Quality (AHRQ)

AHRQ's mission is to improve the quality, safety, efficiency, and effectiveness of healthcare by sponsoring, conducting, and disseminating research that relates to the aforementioned mission.¹³ AHRQ has a number of disaster-related functions within DHHS, with an emphasis on bioterrorism (BT)-related issues. The organization has funded BT-related research, conducted a variety of audio conferences for clinical providers, issued evidence-based practice reports, and distributed issue briefs based on the audio conferences. AHRQ also provides technical support to ASPHEP during responses.

Centers for Disease Control and Prevention (CDC)

The CDC is the world's foremost public health organization, and it has had significant experience in responding to disasters and public health emergencies globally.¹⁴ It also has a major role in disaster response mitigation through its leadership in disease prevention activities. CDC is the national leader in the areas of epidemic outbreak response, disease surveillance, environmental health, public health laboratory readiness, and public communications. In conjunction with the Agency for Toxic Substance and Disease Registry, the CDC serves as the DHHS lead for infectious disease response, chemical/hazardous materials exposure, vector control, radiological monitoring, and public (risk) communications. Additionally, the CDC has the lead scientific responsibility for the SNS.

CDC epidemiologists and other response team personnel deploy in support of public health incidents. These personnel perform case investigations and contact tracing, assist with surveillance, and serve as technical advisors for issues such as vector control. CDC laboratories can perform specialized assays to identify biological and chemical agents from clinical and, in some cases, environmental specimens. CDC also manages the Laboratory Response Network (LRN) for BT and a national network of public health laboratories, each capable of performing sophisticated testing of infectious agents. Participants in the LRN program receive training, protocols, supplies, and a secure reporting system.

Public communications can occur through a variety of CDC venues. The *Morbidity and Mortality Monthly Report (MMWR)* has long been recognized as a periodical that serves to notify and update professionals about public health investigations and incidents. CDC also developed two other lines of communication. The Health Alert Network (HAN) and the Epidemiologic Exchange (Epi-X) were developed as web-based communications networks. HAN is used to distribute information through a widespread open network. Epi-X is more secure and is directed to epidemiologists and other

public health professionals at the federal, state, and local levels. CDC also conducts provider training through on-site courses and teleconferences.

CDC maintains a state-of-the-art emergency operations center that serves as the information-gathering center for the agency and maintains 24-hour, daily access for local, state, and federal agencies.

Food and Drug Administration (FDA)

The FDA's stated public health mission is "assuring the safety, efficacy, and security of human and veterinary drugs, biological products, medical devices, our nation's food supply, cosmetics, and products that emit radiation."¹⁵ The FDA regulates the safety of biologics (including the blood supply), cosmetics, drugs (prescription and over-the-counter), foods (except meat and dairy products), medical devices, radiation-emitting electronic products, and veterinary products. The FDA also has the responsibility for animal health, as it relates to food safety and security.

The FDA has investigated foodborne outbreaks and medication tampering and has supported DHHS response to domestic disasters. In recent years, the FDA has played a major role in the preparedness activities against terrorism and has organized several new offices to facilitate its activities. The Office of Crisis Management (OCM) coordinates FDA emergency response activities. The Office of Emergency Operations within OCM coordinates FDA field and headquarters activities and maintains the FDA emergency operations center.

The FDA maintains expertise to assist in areas of food safety, including the production, processing, storage, and holding of domestic and imported foods. It has worked with other federal agencies to implement a national laboratory network capable of responding to a food security incident. FDA uses field personnel to perform food import examinations at approximately 90 U.S. ports. FDA collaborates with U.S. blood banks to ensure the continuous supply of safe blood. It also works with other DHHS agencies and the pharmaceutical industry to help guide the development of new medical countermeasures for BT. Recent new regulations have facilitated the FDA approval process for new products and medical countermeasures. The FDA works with other federal agencies in developing guidance for using these countermeasures in special populations or when there is no FDA-approved product or no approved indication for a marketed product; devices under investigational new drug (IND); and investigational device exemption (IDE) applications. The FDA works with other federal agencies in developing guidance for countermeasure use in special populations or when there is no FDA-approved product or no approved indication for a marketed product.

Health Resources and Services Administration (HRSA)

HRSA's involvement in disaster response has largely been the issuance of grants to improve hospital BT preparedness. HRSA grants have provided funding through state health departments to address surge capacity, communications, decontamination, and exercises related to hospital operations.¹⁶

The Federal Occupational Health office is a component of HRSA that provides clinical services, environmental health services, and employee assistance programs for federal workers. Personnel from this organization have provided postdisaster clinical and counseling services to federal employees at disaster field offices, regional offices, and headquarters.

Indian Health Service (IHS)

The IHS has provided leadership in addressing disasters affecting the health and medical systems directly associated with tribal nations and reservations.¹⁷ In the Hantavirus outbreak on the Navajo reservation, IHS medical personnel were active participants in the response. (Hantavirus disease was virtually unknown in the Americas until 1993, when a physician at IHS in New Mexico reported that two previously healthy young people had died from acute respiratory failure.)^{17a} Tribal leaders and medical personnel have been actively engaged with their state counterparts in preparing for BT. The IHS Office of Surveillance was established in 2002 to address public health needs associated with disease outbreaks and BT. IHS personnel have also been deployed to domestic events.

National Institutes of Health (NIH)

NIH's role in the nation's health response system has been parsed out to a variety of its 27 institutes and centers. The NIH mission relates to the stewardship of medical and behavioral research.¹⁸ Its National Institute of Mental Health supports research in the area of response to trauma and violence.¹⁹ The National Institute of Environmental Health Sciences supports research directed at the health consequences of environmental toxins.²⁰ NIH also supports and performs research that enhances the understanding of the basic biology and mechanisms of immunological response to particular biological agents. The National Institute of Allergy and Infectious Diseases (NIAID) has the NIH lead on many of these activities and receives substantial funding within DHHS to accelerate development of new and improved vaccines, diagnostic tools, and therapies against potential agents of BT.²¹ NIH has also been dedicated to the expansion of the medical countermeasures for biological agents of terrorism. NIAID has created the Office of Biodefense Research and the Biodefense Clinical Research Branch in the Office of Clinical Research. In addition to the research activities, NIH sponsors regional centers for biodefense research and biocontainment laboratories.

Substance Abuse and Mental Health Services Administration (SAMHSA)

SAMHSA provides the coordination of federal mental health services for the government. SAMHSA assists in the assessment of mental health needs and the identification of mental health services that can be provided to those affected by disasters. SAMHSA provides grants to states that assist in training mental health counselors and

enhancing mental health response capacity.²¹ It also produces publications related to planning and preparedness and the mental health impact of disasters as well as training manuals for mental health responders. SAMHSA maintains a technical assistance center that can be accessed by responders.

Commissioned Corps of the U.S. Public Health Service

Headed by the U.S. Surgeon General, the CC consists of more than 6000 commissioned officers who have degrees in health- and medical-related professions.²² CC officers are distributed among all of the DHHS Operating Divisions and can be assigned to other federal agencies. The CC serves as the healthcare corps for the U.S. Coast Guard. CC personnel have responded internationally to a full spectrum of disasters. Two specific units merit discussion: the USPHS DMAT and the CC Readiness Force (CCRF). The USPHS DMAT has been the prototype for all subsequent DMATs and has been one of the most deployed federal medical response units to domestic disasters. The CCRF, consisting entirely of USPHS officers, is a readily deployable force of more than 3000 that can be sent into a variety of health and medical emergencies.²³ CCRF personnel receive training similar to that of the NDMS response teams and must meet additional requirements beyond those of other USPHS officers. Deployed CCRF personnel must rely on the host organization to provide food, shelter, water, sanitation, local transportation, and communications.

Department of Veterans Affairs

The DVA is a cabinet-level agency with three primary divisions: Veterans Benefits Administration, National Cemetery System, and the Veterans Health Administration (VHA). VHA is the largest healthcare system in the United States. Within its 21 Veterans Integrated Service Networks (VISNs) are more than 150 hospitals, 800 clinics, and 400 additional facilities, such as counseling centers. VHA employs more than 15,000 physicians and nearly 200,000 other healthcare professionals. VHA principally exists to provide medical care to military veterans. It also has important roles in medical research and the education of the healthcare workforce.

Its fourth mission is that of emergency management.²⁴ In that capacity it supports medical operations as a backup for DoD (through the Integrated Continental United States Medical Operations Plan), as a supporting agency under the NRP, as a partner to the NDMS, and for continuity of governmental operations functions. VHA also has a unique role in fielding emergency medical response teams for radiological emergencies.

Interagency coordination and policy matters related to emergency management and response reside at the secretary level, but day-to-day management and oversight comes from the Emergency Management Strategic Healthcare Group (EMSHG). EMSHG is headquartered in Martinsburg, W.Va., and it has a peripheral staff composed of three district and 37 area emergency managers. These peripheral staff members coordinate all emer-

gency management activities within the VISNs and subordinate facilities.

VHA personnel have deployed to the vast majority of national disasters in the last decade, including the response to the New York City terrorist attack of 2001. These personnel have also provided support to National Security Special Events (NSSE), such as presidential inaugurations and the Olympic Games.²⁵

Executive order 12657 places an additional responsibility on the VHA to provide medical response to incidents involving radiological emergencies.²⁶ VHA has the 25-member Medical Emergency Radiological Response Team (MERRT), which can arrive at the site of a radiological emergency and is self-sustaining. As such, it is not a first response organization, but rather it provides supplemental medical care at hospitals and technical assistance and guidance in decontamination and monitoring. When MERRT is deployed, it is considered a federal resource.

Several VISNs also have developed 80-member, multidisciplinary Emergency Medical Response Teams (EMRTs), which are not self-sustaining and are not considered federal resources. These teams were developed primarily to provide augmentation capabilities within the VISN area of responsibility. They could, however, be used in response to a remote national disaster under other deployment venues.

A current initiative within VHA is the population of the Disaster Emergency Medical Personnel System (DEMPS) database. DEMPS is a voluntary enrollment of full-time VHA employees who have agreed to deploy if requested to a disaster site to augment capabilities. This program is in its infancy as of this writing.

VHA also has a role in federal disaster cache management. In addition to its role as logistical manager of SNS caches, VHA maintains caches for its facilities' use, and by extension, these could be used in community-wide disasters. It also maintains caches for NSSE events as well as a stockpile for response involving disasters that would affect the U.S. Congress.

VHA probably has its greatest role in local emergency management. VHA operates the majority of the NDMS FCCs. Additionally, VHA hospitals are charged with assisting local community healthcare resources in their preparedness and planning. Finally, as part of the community healthcare network, VHA resources would be automatically drawn into the response to a local disaster, such as what occurred in Houston, Texas, in 2000, when VHA facilities accepted transferred patients from area civilian hospitals incapacitated as the result of flooding.

Department of Defense

The DoD is identified as a support agency for nearly all of the 15 Emergency Support Functions identified in the NRP. Its component services have large amounts of material and personnel resources that could be brought to bear in response to a disaster, anywhere in the world. The Army Civil Affairs branch (primarily found in the Reserves component) even has expertise in governmental function reestablishment. In addition to the active duty component, DoD can call on Reserve forces of all

the services, and, under certain circumstances, can federalize Army and Air Force National Guard personnel as part of its military response. To chronicle all of the many assets would far exceed the scope of this chapter.

DoD support to federal, state, or local emergency managers is governed by a number of statutes and executive orders, collectively referred to as “Military Support to Civil Authorities” (MSCA).²⁷ General guidance for the use of MSCA includes the following:

- Civil resources are applied first.
- DoD resources are provided only when requirements are beyond the capabilities of civil authorities.
- Specialized DoD capabilities requested for MSCA are used efficiently.
- Military operations other than MSCA will have priority over MSCA.
- National Guard forces that are not in federal service have primary responsibility for providing military assistance to state and local government agencies in civil emergencies.
- DoD and the military services will not procure or maintain any supplies, material, or equipment exclusively for providing MSCA.
- In general, DoD resources will not be used for law enforcement or intelligence-gathering functions.

Imminently serious conditions resulting from any civil emergency or attack may require immediate action by military commanders to save lives, prevent human suffering, or mitigate great property damage. When such conditions exist and time does not permit prior approval from higher headquarters, local military commanders are authorized to take necessary action to respond to requests of civil authorities. This is commonly referred to as “Immediate Response.”

Under the MSCA doctrine, and in line with the NRP, requests for military support are submitted by lead federal agencies (LFAs) through FEMA to the Joint Director of Military Support (JDOMS) on the Joint Chiefs of Staff. The JDOMS has the authority to task Unified Combatant Commanders, services, and defense agencies to provide MSCA support for presidentially declared disasters and emergencies. The JDOMS validates requests for military assistance from LFAs, and plans, coordinates, and executes DoD civil support activities. The JDOMS controls a joint staff to conduct operations during declared disasters.

Operationally, MSCA is directed through the U.S. Northern Command (USNORTHCOM) in Colorado Springs, Colo., through an operational Joint Task Force-Consequence Management (JTF-CM).²⁸ The two continental armies of the United States (First Army and Fifth Army) have response task forces that can deploy to the vicinity of the disaster and assume operational control over all military forces assigned to the response. In addition, USNORTHCOM has a standing task force, the Joint Task Force-Civil Support (JTF-CS), that was established specifically for the homeland defense mission.

DoD resources fall into two broad categories: (1) mass resources that can augment similar capabilities in the other federal agencies and (2) unique resources that can provide expertise and technical assistance. Mass resources of interest to civilian medical planners would include:

- More than 75 military hospitals and more than 100,000 public health and healthcare professionals
- Deployable medical platforms, ranging in size from the U.S. Air Force’s air transportable Expeditionary Medical Support (which can be expanded up to 25 beds each) to the two U.S. Navy 1000-bed hospital ships
- Significant air assets that can be used to evacuate casualties, as described in the section on the NDMS
- Caches of pharmaceuticals and medical supplies, referred to as wartime stocks; these would only be mobilized for MSCA missions in the most unusual circumstances
- Specialized resources²⁹ that may be brought to bear in the event of an overwhelming disaster:
 - Deployable public health laboratories
 - Specially trained response teams, such as the U.S. Army Chemical and Biological Special Medical Augmentation Response Teams (C/B-SMART), the U.S. Navy Special Psychiatric Intervention Teams (SPRINTs), or the U.S. Air Force Radiation Assessment Teams (AFRATs)
 - Reach-back expertise capabilities through the U.S. Army Medical Research Institute of Infectious Disease (USAMRIID) and the Medical Research Institute for Chemical Defense (USAMRICD), the Armed Forces Radiobiological Research Institute (AFRRI), or the Armed Forces Institute of Pathology (AFIP)

Other specialized capabilities exist within the DoD due to its combat mission. For example, the Technical Escort Unit (TEU), which is trained and equipped to handle extreme hazardous materials and radiation sources, forms the nidus of the much larger Guardian Brigade, which has specific homeland defense functions. The U.S. Marine Corps includes the Chemical and Biological Immediate Response Force (CBIRF), a 350-member rapid response unit trained to work in hazardous environment operations, including patient extrication, decontamination, and emergency stabilization and treatment.

American Red Cross

Chartered by Congress in 1905, the Red Cross³⁰ has as its mission to “. . . carry on a system of national and international relief in time of peace and apply the same in mitigating the sufferings caused by pestilence, famine, fire, floods, and other great national calamities, and to devise and carry on measures for preventing the same.” Each year, the ARC responds to more than 60,000 disasters of various sizes and complexities. ARC is the LFA for the Mass Care Emergency Support Function of the NRP and has supporting roles in the Public Health and Medical Services Emergency Support Function.

ARC provides shelter, food, and health and mental health services to address basic human needs. Family and individual assistance is also given to those affected by disaster to enable them to resume their normal daily activities independently. ARC also feeds emergency workers, handles inquiries from concerned family members outside of the disaster area, provides blood and blood products to disaster victims, and helps those affected by disaster to access other available resources.

ISSUES IN FEDERAL RESPONSE TO DISASTERS

With its many resources and vast expertise, the U.S. government has the capabilities and capacities to effectively respond to virtually all but the most cataclysmic disasters imaginable. There are, however, a number of issues that remain unresolved. Some of these include:

- **Response time:** Identifying, activating, and mobilizing these resources may take considerable time, and local response agencies should not anticipate significant federal support to be on-site and fully operational for 24 to 48 hours, especially at remote locations or those whose transportation infrastructures (airfields, railways, or highways) have been compromised due to the disaster.
- **Identification of appropriate resources:** In general, federal resources have been designed for primary functions other than disaster response and relief. As a consequence, no two response teams are identical in capabilities. Requests for federal resources must be in the form of a capabilities request, as opposed to a platform, and identifying specific agency resources to meet those requested needs may slow response. Resource typing, which is currently under way through the National Incident Management System (NIMS) construct, could address this issue.
- **Command and control:** With the exception of forensic and other law enforcement functions in the case of a terrorist event, federal resources are to augment state and local authorities. With numerous response organizations from all levels of government, each operating by its own protocols and procedures, collaboration and integration during high-tempo operations may at times be problematic. Again, NIMS was designed to alleviate some of the previous problems with command and control.

SUMMARY

The U.S. government, through its many federal agencies, has a wealth of capabilities and capacity to respond to natural, technological, or terrorist-induced disasters. These resources may be accessed through a process to respond at the request of local or state civil authorities. Challenges continue to exist in command and control, coordination, and access of these resources in a timely manner.

International Disaster Response

Dan Hanfling, Craig H. Llewellyn, and Frederick M. Burkle, Jr.

Global disasters—natural, technological, and terrorist-related—occur almost daily, resulting in significant human, economic, and environmental consequences. Recent disasters have highlighted the need for the United States to be able to provide rapid, responsive, and sustainable disaster relief in the international setting. During the past quarter century, earthquakes alone have caused more than 1 million deaths worldwide.¹ In just the past 5 years, three catastrophic earthquakes occurred in Izmit, Turkey (17,118 deaths; more than 50,000 injured); Gujarat, India (20,000 deaths; more than 167,000 injured); and Bam, Iran (43,200 deaths; more than 30,000 injured).² In December 2004, the cataclysmic tsunami that swept across Southern Asia killed an estimated 200,000 to 300,000 people and displaced more than 1.1 million people. Moreover, since the end of the Cold War, the world has witnessed an increase in the number of complex emergencies (CEs). These may be defined as intrastate conflicts resulting from administrative, economic, political, and social decay and are marked by intense violence, often pitting cultural, ethnic, or religious groups against one another.³ More than two decades of ongoing armed conflict in the Islamic state of Afghanistan recently culminated in military intervention by the United States and Great Britain in the war on terrorism. More than 5 million Afghans live as refugees or internally displaced persons and are greatly in need of the basic minimum resources necessary to maintain health and well being.⁴ At its worst, the genocidal spasms of violence in Bosnia-Herzegovina (1992-93), Rwanda (1994), and Chechnya (1994 to present) and the recent crisis in Darfur, Sudan, represent the embodiment of the need for rapid, coordinated, international disaster response. In the current crisis in Sudan, hundreds of thousands of refugees, with limited access to international assistance, are at risk of dying as a result of the political upheaval, severe drought and famine, and sluggish international intervention.⁵

Beyond death and destruction lie families in ruin; communities torn asunder; and basic social, economic, and medical needs left unmet. Into such voids created by CEs, there quickly mobilizes an international disaster response capability composed of government, non-government, and international agencies and military elements. The goals of such efforts include the provision of

adequate food, clean water, shelter, sanitation, and basic medical care. Such basic care may be augmented by specialized response capability, such as search and rescue,⁶ surgical response,⁷ or public health technical assistance.^{8,9} The intent of this chapter is to briefly review the components of an international disaster response mounted by the U.S. government (USG) in conjunction with the United Nations (UN), UN agencies, the Red Cross, nongovernment organizations (NGOs), and other providers of humanitarian assistance (HA).

CURRENT PRACTICE

U.S. Government's Role in Response to International Disasters

Under Section 491 of the Foreign Assistance Act of 1961, the USG is provided the flexible authority that permits the U.S. Agency for International Development (USAID) to respond to the needs of disaster victims upon an official state-to-state request initiated by the country seeking assistance. The U.S. president designates the USAID administrator as the special coordinator for international disaster assistance. The Bureau for Democracy, Conflict and Humanitarian Assistance (DCHA) and its Office of Foreign Disaster Assistance (OFDA) are chiefly responsible for the coordination and implementation of all official USG disaster assistance efforts.

OFDA's mandate is to "save lives, alleviate suffering, and reduce the economic impact of disasters." This is primarily accomplished in coordination with the government of the affected country, other donor governments, international organizations, UN relief agencies, private voluntary organizations (PVOs), and NGOs. The initial responsibility for disaster relief rests squarely with the government of the affected country. OFDA only responds when the United States and the affected country declare a disaster using the following criteria. First, the magnitude of the disaster exceeds the affected country's capacity to respond. Second, the affected country has requested or will accept U.S. government assistance and such assistance is deemed to be in the interest of the USG.¹⁰

After the official declaration of disaster and request for USG assistance, OFDA has a discretionary fund of up to \$50,000 that can be made immediately available to meet initial relief needs. The use of this Disaster Assistance Authority is intended solely to initiate assistance efforts. OFDA has several options beyond the provision of monetary assistance. With the approval of the affected country's government, the U.S. Embassy may request that OFDA deploy one or more regional advisors or an assessment team to the disaster site or send a disaster assistance response team (DART) to provide direct coordination in the management of USG assistance (Boxes 15-1 and 15-2).

OFDA has regional advisors attached to USAID missions throughout the world, specifically covering the Europe/Middle East, Asia/Pacific, and Latin America/Caribbean regions. These disaster relief experts can draw on public and private sector resources to respond within 24 hours of a disaster event worldwide. Fairfax County, Va., and Los Angeles County, Calif., have specialized teams experienced in search and rescue, medical assessment and response, operational leadership, and logistical support available to OFDA. Fairfax County Virginia International Search and Rescue Team 1 (referred to as Virginia Task Force 1 in the Federal Emergency Management Agency National Urban Search and Rescue Response System) deployed to the embassy bombings in Nairobi, Kenya (1998), and to the earthquakes in Mexico City, Mexico (1985); Manila, Philippines (1990); Izmit, Turkey (1999); Duzce, Turkey (1999); Toulou, Taiwan (1999); and Bam, Iran (2004).

Especially in the case of response to collapsed structures resulting from a significant seismic event or a terrorist attack, members of the assessment team and DART are often drawn from the ranks of one of the two international search and rescue assets. An assessment team composed of key participants—such as search and rescue, medical, logistics, and technical experts, including a structural engineer—deploy as soon as possible to provide initial on-scene evaluation of the scope and scale of the disaster event. The search-and-rescue team may

BOX 15-1 DISASTER SCENE SITUATION ASSESSMENT

- Area affected by the disaster (location and size)
- Number of people affected by the disaster
- Mortality and morbidity rates
- Types of injuries and illnesses
- Characteristics and conditions of the affected population
- Emergency medical, health, nutrition, water, and sanitation services available
- Level of continuing or emerging threats
- Damage to infrastructure and critical facilities
- Damage to homes and commercial buildings
- Damage to agriculture and food supply system
- Damage to economic resources and social organization
- Level of response by the affected country and internal capacities to cope with the situation
- Level of response from other donor countries and PVOs/NGOs

Adapted from USAID. Field Operations Guide for Disaster Assessment and Response, Version 3.0. Available at: http://www.usaid.gov/our_work/humanitarian_assistance/disaster_assistance/resources/pdf/fog_v3.pdf.

BOX 15-2 OFDA DART RESPONSIBILITIES

Assist U.S. Chief of Mission and USAID Mission (if present) with management of USG response to a disaster by the following methods:

- Provide an operational presence on the ground that is capable of carrying out sustained response activities.
- Develop and, on approval, implement OFDA's field response strategy based on the DART mission objectives.
- Coordinate the movement and consignment of USG relief commodities.
- Coordinate USG relief efforts with the affected country, other donor countries, relief organizations and, when present, military organizations.
- Fund relief organizations.
- Monitor and evaluate USG-funded relief activities.

Adapted from USAID. Field Operations Guide for Disaster Assessment and Response, Version 3.0. Available at: http://www.usaid.gov/our_work/humanitarian_assistance/disaster_assistance/resources/pdf/fog_v3.pdf.

follow, depending on Department of Defense (DoD) airlift support. The search and rescue team is composed of more than 70 members; deploys with more than 58,000 pounds of equipment, including food and water; and can maintain self-sufficiency in an austere environment for 7 to 10 days. In the response to the Izmit, Turkey, earthquake the Fairfax County team conducted reconnaissance in an area that was more than 11 square miles, evaluated more than 70 potential rescue sites, averaged approximately 27 worksites per day, and completed four successful live rescues and more than 40 body recoveries.¹¹

OFDA is not the only office within the USG that provides humanitarian assistance to foreign nations. The Food for Peace Program (FFP), also administered under the direction of USAID, is responsible for coordinating the government's foreign food aid programs, which are authorized under U.S. Public Law 480, Titles I and III. These programs are provided as bilateral grant programs to countries in need of food aid assistance. On the other hand, Title II emergency food aid programs are targeted specifically for populations suffering from "food insecurity as a result of natural disasters, civil conflicts or other crises."¹² Title II programs are provided without request for repayment. Much of this food aid is also coordinated with the U.S. Department of Agriculture (USDA), which works closely with FFP in allocating surplus commodities to developing countries, under Section 416(b) of the Agricultural Act of 1949. This law ensures that the United States helps support emergency feeding programs, especially those related to events of natural consequence, such as drought, and those resulting from the onset of civil strife.

The U.S. Department of State (DOS) also plays a significant role in international disaster response. Whereas OFDA primarily responds to the needs of internally displaced persons (IDPs), the DOS retains chief responsibility for the care and support of refugee populations (those that cross state boundaries) on behalf of the USG. The Bureau of Population, Refugees and Migration (PRM) administers multilateral grants to international relief organizations, such as those operating under the umbrella of the UN. These grants may be requested in response to refugee

emergency appeals. In addition, DOS/PRM regularly contribute to the program budgets of relief organizations.

In response to attacks directed against U.S. embassies in Nairobi, Kenya, and Dar es Salaam, Tanzania, in August 1998^{2,13} and in large part because of the disorganized local response to these events and the absence of trusted medical and surgical capabilities, DOS elected to support the development of an International Medical Surgical Response Team (IMSuRT). Under any disaster circumstances, the already fragile medical infrastructure in developing nations is strained beyond capacity and capability, ultimately resulting in the inadequate delivery of health-care to those in need. IMSuRT deployed to Guam in 2002 after the landfall of the devastating supertyphoon Pongsona to support the delivery of healthcare services on the island and in 2003 was sent to Micronesia in the West Pacific Ocean, again after the effects of a natural disaster. IMSuRT was most recently deployed in the aftermath of the Bam, Iran, earthquake in January 2004.⁷

With respect to international response as a result of terrorist activity, the Presidential Decision Directives (PDDs) issued in 1995 (PDD 39) and 1998 (PDD 62) clearly outline the mechanics of response to terrorist threat or use of weapons of mass destruction in the United States or against U.S. interests abroad. These executive orders clearly reaffirm that DOS is the lead federal agency for foreign consequence management and specify that DOS is responsible for leading and managing the Foreign Emergency Support Team (FEST) and the Consequence Management Response Team (CMRT). The creation of the Department of Homeland Security (DHS) has necessitated a wholesale revision of the domestic response to disaster. However, the newly drafted National Response Plan (NRP) clearly specifies that “the Secretary of State remains responsible for coordinating international prevention, preparedness, response and recovery activities relating to domestic incidents, and for the protection of U.S. citizens and U.S. interests overseas.”¹⁴

The DoD assumes a significant responsibility for providing international disaster assistance. Since the end of the Cold War, there has been increasing involvement of military assets in missions directly related to peacekeeping, disaster response, and humanitarian assistance (Table 15-1). Within DoD, the Office of Peacekeeping and Humanitarian Affairs (PK/HA) has the chief responsibility to work with USAID and DOS as specified by the Denton Amendment, which allows the U.S. military to air-

lift or transport by sea privately donated humanitarian relief commodities on a space-available basis to countries affected by disasters. Some of the capabilities and strengths the military can bring to HA and disaster relief operations include logistical support and heavy lift operations, security, establishment of a communications infrastructure, additional manpower, and the overlay of command and control.

Military operations in support of diplomatic efforts are usually one of two types. “Peacekeeping” missions are undertaken with the consent of all major parties to a dispute. They are designed to monitor and facilitate the implementation of specific agreements, such as a cease-fire or a truce. Their intent is to encourage the continued negotiation, mediation, arbitration, and judicial review required to reach a lasting political settlement. When deployed under a UN mandate, this operation may be referred to as a “Chapter VI operation,” referring to Chapter VI of the UN Charter, titled “Pacific Settlement of Disputes.” A mission that involves the threat or application of military force to achieve compliance with resolutions or sanctions designed to restore peaceful relations between nations may be referred to as a “Chapter VII operation,” referring to Chapter VII of the UN Charter, titled “Action with Respect to Threats to the Peace, Breaches of the Peace, and Acts of Aggression.” Both types of mission profiles often will involve disaster relief activities. However, the military leadership will remain very cognizant of the risk of sustaining “mission creep,” in which the military operation ultimately takes on a broader role or assumes responsibility for elements of the event that initially were not planned.

A command and control element established specifically for such missions, known as a Joint Task Force (JTF), will commonly accompany any large-scale military participation to improve field coordination and integration of the multiple military services involved. In turn, the JTF will often establish the Civil Military Operations Center (CMOC) to coordinate and facilitate humanitarian operations of the United States and any multinational force with those of international and local relief agencies and with the recognized authorities of the affected country. The CMOC may request USAID DART advisors to join the CMOC staff to assist in screening and validating requests for military support from the relief community. DART representatives, who often have previously established relationships with key elements of the international disaster response community, can also assist the military leadership in understanding the capabilities, levels of expertise, and operational methods of the involved relief organizations. DART representatives can also advise and educate the responding relief agencies about the capabilities, operational methods, and priorities of the U.S. military.

Military commanders may elect to establish a Humanitarian Assistance Coordination Center (HACC) to focus specifically on coordination of HA needs. This is done when the CMOC takes on the expanded role of developing other civilian-military initiatives, particularly those related to infrastructure development and the reinstatement of civil authority, such as is the current situation in postwar Iraq. On a related point, the National Security

TABLE 15-1 DoD MISSIONS IN HUMANITARIAN ASSISTANCE OPERATIONS

Northern Iraq	1991-1996
Former Yugoslavia (including Bosnia)	1992-1998
Somalia famine relief	1992
Rwanda refugee crisis	1994
Hurricane Mitch	1998
Kosovo	1999-2000
Venezuela floods	1999
Mozambique floods	2000

Iraq	2003-present
South Asia tsunami	2005

Council (NSC), which serves as the principal forum for national security and foreign policy matters, including those related to humanitarian issues, may play a role in influencing international disaster response. Finally, when needed, the U.S. Geological Survey, the Centers for Disease Control and Prevention, the U.S. Forest Service, and the Environmental Protection Agency all provide technical assistance in response to disasters and potential hazards overseas.

International Organizations and their Role in International Disaster Response

Since its inception, the United Nations has played an important role in the response to and coordination of international disaster relief efforts. Historically, a number of UN agencies have had responsibilities in ensuring coordination among responding nations and NGOs. These have included the United Nations Development Program (UNDP), United Nations High Commissioner for Refugees (UNHCR), United Nations Children's Fund (UNICEF), Food and Agriculture Organization (FAO), World Food Program (WFP), and World Health Organization (WHO). Each of these agencies was created under separate international treaties, is overseen by separate mechanisms of governance, and is funded predominantly by bilateral donor contributions separate from the UN budget. A result of this fractured organizational approach, often compounded by the exigencies of international political "power plays," has been an uneven and sometimes unhelpful UN presence in the response to disaster events and CEs.

In 1991, the UN General Assembly passed UN Resolution 46/182 calling for the improvement and strengthening of humanitarian assistance.¹⁵ This resolution mandated the identification of the UN Emergency Relief Coordinator and resulted in the creation of the Department of Humanitarian Affairs, which in 1998 became the UN Office for the Coordination of Humanitarian Affairs (OCHA). OCHA coordinates response to humanitarian crises, serves as an advocate for HA, and promotes the development of policy supportive of this mission. This includes the facilitation of the relationship between humanitarian and military components participating in a relief operation. OCHA carries out its responsibilities, in part, by providing oversight to the UN Disaster Assessment and Coordination (UNDAC) teams and the International Search and Rescue Advisory Group (INSARAG). UNDAC teams are composed of a mix of international disaster management experts who can be deployed immediately after a disaster event to conduct a rapid assessment of priority needs. This group is expressly focused on providing support to host government authorities and to the UN Resident Coordinator to facilitate international disaster relief coordination. In earthquake responses, the UNDAC is used to coordinate international search and rescue operations. Often, the first international search and rescue team to arrive in-country establishes the On-Site Operations Coordination Center (OSOCC).

With regard to health and medical issues arising from sudden or slow-onset disaster events, WHO has the chief

responsibility as the UN's lead technical agency. WHO is mandated by its constitution to "furnish appropriate technical assistance, and in emergency, the necessary aid upon the request or acceptance of Governments."¹⁶ Along with its regional offices, including the Pan American Health Organization (PAHO), WHO is structured to deliver technical advisory support to national and local authorities, the donor community, and international NGOs. It has an operational role in defining public health priorities and plans of action.

Of all the international organizations involved in humanitarian assistance and disaster response, the International Committee of the Red Cross (ICRC) remains the oldest; largest; and, with its "red cross" symbol, the most universally recognized. It is a Swiss-based organization with a mandate under the internationally accepted Geneva Conventions to act as a neutral intermediary to protect victims of conflict, and by extension, support victims of disaster. It remains separate from all other international humanitarian organizations and NGOs and is neutral with regard to politics, religion, and ideology. The International Federation of Red Cross and Red Crescent Societies (IFRC), also Swiss-based, serves as the umbrella organization for all Red Cross and Red Crescent Societies throughout the world. It comprises 178 member societies, with a secretariat in Geneva, and more than 60 delegations that help coordinate relief efforts in response to natural disasters and assist with refugee populations in flight from areas of conflict. It must be noted that the American Red Cross (ARC), although not a USG agency or organization, is not neutral and is not a member of the IFRC.

Finally, and perhaps most importantly, at least with regard to the overall burden of responsibility assumed for disaster response and HA in CEs, are the PVOs and NGOs. PVOs are private, not-for-profit HA organizations that are involved in economic development and relief activities. These organizations are registered with USAID and are equivalent to NGOs, which is the term normally used by non-U.S. organizations. With an increasing emphasis on the provision of emergency aid, government agencies, the UN, and private donors increasingly rely on NGOs to distribute the bulk of humanitarian aid going to victims of disaster. More than 90% of all relief assistance coordinated by the UN is implemented through NGOs.¹⁷ Well-known groups that specifically address health and medical needs include Medecins sans Frontieres (MSF) ("Doctors without Borders"), the International Medical Committee (IMC), and the International Rescue Committee (IRC). MSF was formed in the late 1960s in direct response to the inept and uncoordinated efforts at providing relief to the Nigerian region of Biafra, which was beset by civil strife, leading to severe disease and starvation. MSF was the first of a number of organizations to take an "activist approach" to providing disaster relief, and it remains an important participant in the international arena. However, the increasing use of military support for humanitarian operations creates a unique conflict for many international relief organizations. Because they are protected in their humanitarian work by international law—provided they maintain humanitarian principles of impartiality, neutrality, and universality—many NGOs will not work with the military of any nation.

Partly in reaction to the increasing reliance on military support for humanitarian response, a multilateral group comprised of members of national and international NGOs, the Red Cross Movement, UN Agencies, and the academic community developed the Sphere Project in 1997. This work was focused on the development of “minimum standards” in six critical areas: water supply and sanitation, nutrition, food aid, shelter and health services, and food security. These minimum standards and an accompanying Handbook are based on two fundamental philosophical beliefs. The first is that “all possible steps should be taken to alleviate human suffering arising out of calamity and conflict.” The second is that “those affected by disaster have a right to life with dignity and therefore a right to assistance.”¹⁹

PITFALLS

Many misperceptions exist concerning the form, content, and mission of responders to disaster events in the international community (Box 15-3). These may result in the import and distribution of too many relief items. This, in turn, may trigger a cascade of unintended consequences. For example, the snack biscuits delivered to the Kosovo IDP settlement camps in 1998 were not popular among the camp residents. They were not eaten and were discarded, subsequently introducing rodent and snake vectors into the camp.¹⁸ It is also critically important to recognize the importance of strengthening local capabilities, particularly those in the health and medical sector, in a proactive manner before disaster strikes.^{20,21}

The most egregious mistakes made include those that result in a wholly inappropriate response effort. These may be marked by an obvious lack of responsiveness to local needs (e.g., the establishment of mass vaccination clinics in place of improving sanitary conditions after a natural disaster). Another example would be the employment of expatriate staff when local skills could have been equally successful. At their worst, response efforts may become a burden to the host government of the affected country. An example would be the deployment of expensive field hospitals that arrive long after the last survivors are rescued from the precipitating event and then depart after a week or two in-country without confirming the re-establishment of the indigenous healthcare delivery sector. In the rush to provide visible action to satisfy the international public, more pragmatic and, ultimately, more useful approaches may be abandoned.

There are a number of barriers that impair the execution of successful disaster response efforts relief. A recent IFRC evaluation of existing international disaster response laws cites the following challenges to response organizations. There is an inconsistency of access to disaster-affected populations. Furthermore, some of these impediments are the result of delays, inefficiencies, and inconsistencies in the facilitation of disaster response by state authorities. In certain instances, this may be due to an under-resourced host government infrastructure being overwhelmed by the impact of the disaster. On the other hand, this may also occur as part of an intended manipulation of the international relief community for political or financial gain.²²

BOX 15-3 MYTHS REGARDING INTERNATIONAL DISASTER RESPONSE

Perception:	Large numbers of foreign medical volunteers are needed.
Reality:	Local populations are usually able to manage immediate lifesaving needs. Only medical personnel with skills not available in the affected country may be needed.
Perception:	All forms of urgently delivered international assistance are needed.
Reality:	Any hasty response not based on a needs-assessment only contributes to the chaos of the event. In many instances, the disaster victims or their local governments or support agencies meet most immediate needs.
Perception:	Epidemics of disease inevitably occur after every disaster event.
Reality:	Epidemics do not spontaneously occur after a disaster. Dead bodies do not pose a threat to trigger the outbreak of infectious disease. The key elements contributory to preventing such an outbreak are improving sanitary conditions and educating the affected population.
Perception:	Food aid is always required after a natural disaster.
Reality:	Food aid is not usually required because natural disasters rarely cause loss of crops.
Perception:	Victims of disaster always need clothing.
Reality:	Used clothing is almost never needed and is often culturally inappropriate.
Perception:	Locating victims of disaster in temporary settlements, including the use of tents for shelter, represents the best means of managing the loss of domicile.
Reality:	Funds spent for the purchase of tents are better applied to the purchase of building materials, tools, and other construction-related support in the affected country.
Perception:	Things are back to normal within a few weeks after a disaster event.
Reality:	The effects of a disaster last a long time. Disaster-affected countries deplete much of their financial and material resources in the immediate postdisaster phase. Successful relief programs gear their operations to the fact that international interest wanes as needs and shortages become more pressing.

Adapted from Noji E. The nature of disaster: general characteristics and public health effects. In: Noji E, ed. *The Public Health Consequences of Disasters*. Oxford: Oxford University Press; 1997:17-18.

In addition, there is often a lack of coordination within and between national and international disaster response entities. In part, this may result from the absence of “institutional memory” as individual participants involved in the disaster response change. As a consequence, large bureaucratic organizations repeat mistakes made in previous response efforts, or worse yet, do not account for the variations in the approach given the organization’s mission. A tragic example of this occurred recently during U.S. military operations in Afghanistan. Human daily rations (HDR) are a high-protein, 2000-calorie ration that were introduced in 1993 for use by the DoD in

humanitarian relief efforts. They are designed to be acceptable by all ethnic and religious groups and are meant to be used as a stopgap feeding asset until the arrival of other foods chosen to meet specific or multiple nutritional deficiencies. The HDRs, placed in highly visible yellow packages, were dropped in Afghanistan at the same time that the DoD was dropping yellow painted cluster bombs. Although this had occurred previously during U.S. military actions in Kosovo, the institutional knowledge of this “work issue” was lost due to military rotations from operational forces.¹⁸

Difficulties are also encountered in the coordination of responsibilities at the disaster site. Standardized protocols that govern such coordination do not exist. A “lack of hand-over planning, incomplete and absent documentation, non-overlap of individual successive job holders, poor communication with beneficiaries, (and a) misunderstanding of expectations” contribute to such problems.²³ Difficulties such as these may be due as much to the barriers existing within the NGO community as they are to the need to improve and strengthen coordination by the appropriate international partners, such as OCHA and other key response agencies in the international arena.

CONCLUSION

The response to international disaster events and humanitarian crises by the USG is an important manifestation of its role in global affairs. Even though such efforts usually reflect the dire need for assistance and support on the part of the affected country, it must be recognized that there are instances in which such participation may appear to be a veiled attempt at influencing foreign governments. The major USG participants, including USAID, DOS, and DOD, must work closely together. They must also work in tandem with the key international organizations involved in disaster response, including key UN agencies, the ICRC, and the many NGOs and PVOs that comprise the backbone of the response community.

Disaster/Emergency Management Programs

Peter Brewster

The public health and medical sector is a crucial element of emergency management. Emergency management is the discipline and profession of applying science, technology, planning, and management to deal with extreme events that can injure or kill large numbers of people, do extensive damage to property and disrupt community life.¹ This chapter describes many of the government and other public agency programs that assist this sector.

EMERGENCY MANAGEMENT (EM) CONCEPTS, PRINCIPLES, AND SYSTEMS

The creation of the Federal Emergency Management Agency (FEMA) in 1980 brought with it a new federal focus on all hazards. FEMA was transferred to the U.S. Department of Homeland Security (DHS) as part of the Homeland Security Act of 2002; however, even before this transfer, FEMA sponsored many educational programs and concepts applicable to the public health and medical sector. These programs, available on-site, through distance learning courses or self-study, focus on the following concepts.

Comprehensive Emergency Management

Comprehensive emergency management (CEM) addresses all hazards through the following four phases of activity:

- **Mitigation:** Examples of activities that occur within the mitigation phase include conducting an analysis of potential hazards, threats, and events; the negative effects these hazards may have on populations, infrastructure, and the operational capabilities of response organizations; and planning the structural and non-structural actions to reduce or eliminate these effects.
- **Preparedness:** Preparedness activities include identification of physical, human, and informational resources needed to offset losses or damage to infrastructure or operating systems. Available resources

are maintained and inventoried, and for those not on hand, arrangements for obtaining them are pre-planned. Public education about hazards and family preparedness are components of preparedness activities, as are training and exercises for organizations with emergency responsibilities.

- **Response:** The response phase begins with incident recognition and generally transitions into the recovery phase once ongoing negative effects of the incident have been stopped. Key response activities include situation assessment, warning and notifications, coordinating with other agencies, setting objectives and priorities, and assigning resources to work on disaster-related problems.
- **Recovery:** Recovery activities begin with determining the operational status of priority community systems and working toward their reestablishment and making disaster assistance services available (financial and mental health services). Final components of the recovery phase are the identifying “lessons learned” and making revisions to future mitigation, preparedness, response, and recovery activities.

Integrated Emergency Management System

To implement CEM, FEMA developed the Integrated Emergency Management System (IEMS). IEMS consists of three fundamental parts: (1) a set of program development steps tied to the four phases of CEM, (2) a philosophy of inclusiveness (those groups that will respond to disasters are brought into the planning process), and (3) a method of organization around functions generic to all disasters, not around specific hazards, agencies, or people.

Incident Command System

As IEMS taught planners to think along functional lines in the early 1980s, the Incident Command (Management) System (ICS) was unveiled. ICS was part of a larger National Interagency Incident Management System (NIIMS) that included standardized training, qualifications

and certification, supporting publications, and technologies.^{1a} The “system” of incident command/management is described in detail elsewhere in this text. The ICS concept formed the backbone of National Incident Management System (NIMS) concepts. The Hospital Emergency Incident Command System (HEICS), developed in San Mateo County, Calif., is a specific adaptation of the ICS system to fixed-site healthcare facilities.

Standardized Emergency Management System

Because the ICS was so successful as a management system for field response, the state of California extended its components, principles, and organizational structure into a statewide model that consisted of five response levels: field response, local government, operational area (county), mutual aid region, and state. The Standardized Emergency Management System (SEMS) was made mandatory for all public sector agencies with emergency responsibilities.² SEMS was aimed at solving interagency coordination problems that occurred in and between Emergency Operating Centers (EOCs) at the various response levels.

Disaster Research

Use of disaster research has improved the effectiveness of the emergency management field(s). Sociological studies and reports on human behavior in disasters have identified the “myths” perpetuated by the media (looting, helpless disaster victims, and so on); pushed the profession away from a hazards focus to a generic focus on functions; and brought gender, ethnic, and special population issues to the forefront. Environmental and physical scientists have made advances in land use policies, structural designs and building codes, and monitoring and warning systems that have improved safety.

FEDERAL PROGRAMS

Cities Readiness Initiative

The Metropolitan Medical Response System programs have been discussed in previous chapters. Twenty cities and the National Capital Region/District of Columbia have been identified to participate in this pilot program, based on demographic characteristics and location. The purpose of the Cities Readiness Initiative (CRI) is to assist these localities in increasing their capacity to receive and disburse medications and medical supplies from the Strategic National Stockpile. One particular focus is on the development of unified, intergovernmental (local, state, and federal) operations plans, training, and exercises.

Bioterrorism Preparedness Program

The U.S. Department of Health and Human Services (DHHS) initiated a multiyear program aimed at upgrad-

ing the preparedness of the nation’s public health and healthcare systems to respond to bioterrorism, other outbreaks of infectious disease, and other public health threats and emergencies.³ The Centers for Disease Control and Prevention (CDC), Health Resources Services Administration (HRSA), and Agency for Healthcare Research and Quality (AHRQ) have combined forces to ensure the most effective use of resources.

The umbrella structure for the program concentrates on the following “focus areas:”

- Preparedness planning and readiness assessment
- Surveillance and epidemiology capacity
- Laboratory capacity—biological agents
- Laboratory capacity—chemical agents
- Health alert network/communications and information technology
- Communication of health risks and health information dissemination
- Education and training (criteria included below)
- Cross-cutting initiatives (integration point for the National Disaster Medical System and Metropolitan Medical Response System programs as well as small-pox preparedness and mental health services)

As part of this program, HRSA administers a grant program aimed at increasing the surge capacity of America’s hospitals.⁴ Until now, the healthcare industry has not received significant financial support for emergency preparedness activities. These funds along with grant guidance, existing hospital preparedness standards, and training available through AHRQ and other sources will help to ensure a more effective nationwide emergency management capability.

Domestic Preparedness Program

The Department of Justice’s Office of Justice Programs, in conjunction with the National Domestic Preparedness Program, funds the purchase of specialized equipment for fire, emergency medical, and hazardous materials response services and law enforcement agencies. The purpose of these funds is to enhance the capabilities of jurisdictions to respond to acts of terrorism involving chemical and biological agents and radiological, nuclear, and explosive devices. Early grants paid for a needs assessment, which formed the basis of statewide strategy—a “roadmap” identifying where grant funds would be targeted.

The Homeland Security Act of 2002 transferred the Domestic Preparedness Program to the DHS. DHS’s Office for Domestic Preparedness (ODP) is the primary agency at the federal level for managing the preparedness of the United States for acts of terrorism. ODP responsibilities include coordinating federal preparedness efforts; working with all state, local, tribal, parish, and private sector emergency response entities designated to combat terrorism; and providing support for training, exercises, and equipment.⁵ ODP administers a number of grant programs, exercises, training, and technical assistance services to support state and local emergency responders.

Military Medical Educational Resources

Research and development centers within the Department of Defense (DoD), specifically the U.S. Army Soldier and Biological Chemical Command (SBCCOM),⁶ U.S. Army Medical Research Institute of Infectious Diseases (USAMRIID),⁷ and U.S. Army Medical Research Institute of Chemical Defense (USAMRICD),⁸ remain the preeminent authorities and sources for chemical, biological, radiologic/nuclear, and explosive agent countermeasures. These agencies also offer educational programs to the civilian sector.

UNIVERSITY PROGRAMS

Disaster Research Centers

The Disaster Research Center (DRC) was established at Ohio State University in 1960 and moved to its current location at the University of Delaware in 1985.⁹ DRC directors and staff are some of the best-known sociologists in the field, contributing to practitioners' knowledge of how individuals, family units, organizations, communities, and society as a whole behave when faced with emergency situations. The Natural Hazards Research and Information Applications Center ("Hazards Center") at the University of Colorado in Boulder has been at the forefront of establishing effective linkages between the disaster research community, policy makers, and practitioners.¹⁰ The Hazards Center provides a clearinghouse function for disaster research centers from around the world.

Emergency Management Degree Programs

The University of North Texas offered the first four-year degree program in emergency management before the 1990s. Through FEMA's Higher Education Project, many state and private colleges and universities offer a full range of degree programs based on the sample course modules that FEMA has produced.¹¹ Although hazards have increasingly been added to the curricula of schools of geography, land use planning, public health, and nursing, medical school curricula are lacking sufficient knowledge matter in emergency preparedness to provide a uniform baseline for physicians.

STANDARDS

ASTM 1288 and E54 Committee on Homeland Security

The American Society for Testing and Materials (ASTM) is one of the largest organizations that develop voluntary standards through objective, consensus processes. ASTM 1288, Standard Guide for Planning for and Response to a Multiple Casualty Incident, elucidates emergency medical service and hospital coordination and operations issues.¹² The ASTM Committee E54¹³ on Homeland Security is developing standards and guidance in the following homeland security applications: protecting borders, ports,

and transportation systems; advancing and harnessing science and technology; protecting the nation's infrastructure; and preparing for and responding to national emergencies. Seven subcommittees focus on the following areas: chemical, biological, radiological, nuclear, and explosive (CBRNE) sensors and detectors; training and procedures; decontamination; personal protective equipment (PPE); building and infrastructure protection; security controls; and threat and vulnerability assessment.

NFPA 99, 1600

The National Fire Protection Association (NFPA) is another global developer of consensus standards. The NFPA standards process involves technical committee product requests for proposals from members of the committee and the public, review of proposals and voting by the committee, development of draft standards, request for public comment, final review of comments, and voting by the committee to arrive at a final draft of a standard every five years.

The original emergency preparedness standard for hospitals was drafted by an NFPA Technical Committee in 1975 (NFPA 99), and it remains a leading reference to this day.¹⁴ In the early 1990s, federal, state, and local government and private sector emergency planners began developing recommended practices for disaster/emergency management and business continuity programs (NFPA 1600). NFPA 1600 has been the framework for the state and local Capability Assessment for Readiness (CAR) (1997) and the Emergency Management Accreditation Program (EMAP) (2000).¹⁵ In 2004, NFPA 1600 was recognized as the nation's preparedness standard by the National Commission on Terrorist Attacks Upon the United States (also known as the 9-11 Commission).^{16,17}

Joint Commission on Accreditation of Healthcare Organizations Environment of Care Standards

The Joint Commission on Accreditation of Healthcare Organizations (JCAHO) is the leading developer of standards for the healthcare industry in the United States. Without JCAHO accreditation (for those organizations using JCAHO standards), healthcare organizations cannot receive reimbursement for services under Medicare and Medicaid. The Environment of Care (EC) standards are designed to support a safe environment for patient care and consist of safety, hazardous materials and wastes, fire safety, medical equipment, utility systems, security, and emergency management. The JCAHO emergency management standards (EC 4) reflect the core concerns of mainstream emergency management agencies with those of the healthcare industry.¹⁸

SUMMARY

The management of routine, daily emergencies in the United States is handled at the local level by law enforcement, fire, rescue, hazardous materials, and emergency

medical service providers. When disasters occur, many other organizations may also get involved.¹⁹

Emergency managers work to improve the ability of individuals and groups to solve the problems created during emergencies and disasters. The problem-solving capacity is enhanced by creating structures and procedures that can collect, organize, and allocate information and resources; identify problems; determine objectives and priorities; and assign available resources. These arrangements are built through a regular process in which various agencies interact to identify hazards, develop plans and training programs, establish communications and support facilities, and practice through drills and exercises.²⁰

chapter 17

Community Hazard Vulnerability Assessment

James C. Chang

The community hazard vulnerability assessment (HVA) is the systematic examination of the multitude of hazards, their individual probabilities, and consequences that may be encountered in the community. This assessment requires an in-depth knowledge of the community and is typically performed by a multidisciplinary team. The HVA is often used as the basis for the community's emergency management program.

Like the hospital-based HVA presented in Chapter 18, the community HVA helps emergency planners define the universe of potential threats that the community may face. As with the hospital-based example, community leaders face the same challenges of budgeting, limited resources, and selection of hazards on which to focus their resources. Unlike the hospital-based HVA, however, the scope and performance of a community HVA are often beyond the direct control (and sometimes, influence) of hospital-based planners and are conducted by local emergency management officials.

For a healthcare facility to develop a successful emergency preparedness program and meet its obligations to provide care to the members of the community, it must engage with community planners and response agencies, since healthcare facilities are integral components of the community.

HISTORICAL PERSPECTIVE

To understand where the practice of HVA arose, one must look at the short, fragmented history of emergency management in the United States.

After a devastating fire in Portsmouth, N.H., that overwhelmed both local and state resources in 1803, the U.S. Congress established the precedent for federal aid that is in place today by passing legislation allowing federal resources to be used to support state and local governments. Congress passed 128 other similar pieces of ad hoc legislation in support of victims of the 1906 San Francisco earthquake and other major disasters between 1803 and 1950.¹

In 1916, civil defense programs were born when Congress enacted the U.S. Army Appropriations Act.

This act established the Council of National Defense (CND) with subordinate state and local defense councils in response to a perceived enemy threat. Much of the interest in civil defense ceased with the end of World War I.

After a brief hiatus, federal agencies were given the authority to respond to specific disasters. In 1933, the Reconstruction Finance Corporation was given the authority to fund the repair and/or reconstruction of public facilities damaged by earthquakes. In 1934, the Bureau of Public Roads was given the authority to provide grants to repair federal-aid highways and bridges damaged by natural events (i.e., primarily floods). A noteworthy change in the approach from response to proactiveness (preparedness) occurred with the Flood Control Act of 1936. This act allowed the U.S. Army Corps of Engineers to proactively construct dams, dikes, and levees to reduce local vulnerability to floods.¹

Continuing in the track of responding to actual or perceived emergencies, in 1941 the CND was dissolved and the Office of Civil Defense was established. As with the CND, the focus of the Office of Civil Defense was the establishment of protective services programs oriented toward a specific (i.e., enemy) threat. These activities included the establishment of the Civil Defense Corps, which coordinated the activities of approximately 10 million volunteers and 44 state and 1000 local councils. The Office of Civil Defense was abolished with the end of World War II.¹

The Federal Civil Defense Administration (FCDA) was established by President Truman in 1949 in response to increasing Cold War concerns. The Federal Civil Defense Act of 1950 was quickly passed to give the FCDA the authority and resources to begin planning and coordination activities. One of the most noteworthy successes of the FCDA and its new director, Val Peterson, was the idea that civil defense activities such as disaster planning had a peacetime value. Meanwhile, Congress continued to reinforce the role of the federal government in responding to (but not preparing for) disasters with the Federal Disaster Act of 1950. This act, intended for "getting assistance to rebuild the streets and farm-to-market highways and roads,"¹ was viewed by many as Congress's establishing the legal basis for a continuing

federal role in disaster relief.¹ Subsequent acts, including the Disaster Relief Acts of 1970 and 1974, reinforced the federal government's role in disaster relief.

In 1972, the Office of Civil Defense, which had been reestablished in 1961, was renamed the Defense Civil Preparedness Agency. Increasing international tensions and growing stockpiles of nuclear weapons gave rise to the concept of Crisis Relocation Planning (CRP). The premise behind CRP was the dispersal of the populace from high-risk areas in times of heightened international tensions; in essence, this was an extension of existing hurricane evacuation programs that many coastal areas had successfully developed. In 1974, Congress passed the Disaster Relief Act of 1974 that specifically authorized the federal government to assist in disaster preparedness activities.

Difficulties in implementing CRP and the resulting frustrations experienced by federal, state, and local emergency planners led to a study and report by the National Governor's Association (NGA) in 1978 calling for a coordinated federal policy and approach to emergency planning. The NGA report introduced the concept of comprehensive emergency management (CEM), which is the cornerstone for emergency management today. In response to the NGA report and pressure from the constituency, President Jimmy Carter established the Federal Emergency Management Agency (FEMA) in 1979 to pull together many fragmented federal programs and implement a CEM program.

The new agency, under Director Louis Giuffrida, adopted a position calling for an enhanced civil defense program with an improved ability to deal with natural disasters and other large-scale domestic emergencies. In response to continued skepticism and outright resistance to CRP, the new agency abandoned CRP in favor of CEM. Under CEM, instead of focusing on specific scenarios and their consequences (e.g., nuclear attack, earthquake, or flood), local and state agencies were now encouraged to ask the following:

- What hazards confront our community?
- What resources are available? What needed resources are not available? Over what period of time could local government reasonably acquire these resources?
- What mitigating actions could be taken to reduce future vulnerabilities?

These questions are integral to an Integrated Emergency Management System (IEMS) approach; IEMS is the tool under which FEMA implements CEM. Under IEMS, emergency managers perform systematic assessments of both hazards and response capabilities. Gaps are identified, and then multiyear remediation plans, along with hazard mitigation and recovery plans, are created to address these gaps. Implicit in the use of IEMS is the change from a reactionary to a proactive approach to emergency management. This planning approach facilitates the transition from a hazard-specific to an all-hazards approach to emergency management.¹

CURRENT PRACTICE

To properly plan for emergencies in the community, it is necessary to identify the list of potential hazards, their

probability or relative risk, and their consequences. This HVA helps the planning team decide what hazards merit special attention, what actions must be planned for, and what resources are likely to be needed.

To better describe the community HVA process, it will be broken down into the following actions:

- HVA team membership
- Hazard identification
- Hazard profiling (probability and consequences)

HVA Team Membership²

A team approach should be considered for both the HVA and the development of the final Emergency Operations Plan for many reasons, including:

- To share (synergistic) expertise
- To develop and foster teamwork and working relationships
- To ensure that a holistic view of hazards is taken
- To create a sense of ownership and buy-in from all parties

The constituency of the teams will differ depending on their stated purpose (e.g., HVA versus plans development). Prospective members of the HVA team may include representatives from:

- Emergency Management Agency
- Community leadership (e.g., city manager, county executive)
- Each community public safety agency (law enforcement—police department, sheriff's office; fire department; emergency medical services [EMS])
- Hospitals and other community healthcare facilities
- Public health agencies (local health department)
- Planning departments or agencies
- Public works
- Local Emergency Planning Committee (LEPC)
- Professional groups (e.g., Certified Hazardous Materials Managers, American Society of Safety Engineers)
- Special hazards occupancies or operations (e.g., military bases, industrial complexes, dams, nuclear power plants)
- Major business entities
- Other emergency management planners (e.g., from local, county, regional, or state agencies or private industry)

Hazard Identification

Hazard identification is the exercise of identifying what kinds of emergencies have occurred or could occur within the jurisdiction. For assessment purposes, it may be helpful to divide emergencies into the following categories:

- **Naturally derived emergencies:** (e.g., floods, hurricanes, tornadoes, winter storms)
- **Technologically derived emergencies:** (e.g., power or utility failures, hazardous materials releases, computing systems failures)
- **Manmade emergencies:** (e.g., attacks involving weapons of mass destruction)

A partial listing of potential emergencies is provided in Box 17-1. This listing is not all inclusive, and care must be taken to ensure that hazards are not inappropriately excluded or omitted when assembling the community's overall list of potential hazards.² It is also important to note that hazards may arise from differing sources (e.g., epidemics may be naturally occurring or the result of bioterrorism). Finally, hazards and emergencies may be linked together. For example, a hurricane may generate flooding, mudslides, and loss of utilities.

There are many potential sources of information to support the hazard identification effort, including³:

- Experiences of planning team members
- Experiences of utilities or other major business entities in the community
- Local and/or state Emergency Management Agency records
- Local emergency response agency records
- Newspaper or other historical archives
- Experiences of similar or adjacent communities
- Hazard information maps compiled by FEMA and state emergency management agencies, the U.S. Geological Survey (USGS) and state geological surveys, the National Weather Service (NWS), and the Federal Insurance Administration (National Flood Insurance Program)

BOX 17-1 LIST OF POTENTIAL EMERGENCIES

Naturally Derived

Avalanche
 Drought
 Earthquake
 Epidemic
 Flood
 Hurricane (cyclone, typhoon)
 Landslide
 Mudslide
 Severe thunderstorm
 Temperature extremes
 Subsidence
 Tornado
 Tsunami
 Volcanic eruption
 Wildfire
 Windstorm
 Winter storm (blizzard, ice storm)

Technologically Derived

Airplane crash
 Dam failure
 Hazardous materials release
 Hog or other animal farm waste containment failure
 Information technology system failure
 Power failure
 Radiological release
 Train derailment
 Urban conflagration
 Utility interruption (natural gas, water, sewer, telephone, data)
 Water supply contamination

Manmade

Civil disturbance
 Mass casualty events
 Terrorism (chemical, biological, radiological, nuclear, or high-yield explosive [CBRNE])

- Maps of 10- and 50-mile emergency planning zones (EPZs) around nuclear power plants
- Maps of hazardous materials sites prepared by the LEPC
- Risk management plan submittals by users of extremely hazardous substances
- Local American Red Cross or other disaster relief agency records
- Results of any federal, state, or private hazard analyses
- Local or state historical society or area universities (e.g., departments of history, sociology, geography, engineering)
- Professional or business associations (e.g., insurers, engineers, and builders)
- Engineering assessments (e.g., reliability studies, mean time between failure studies)
- Longtime community residents

Hazard Profiling (Probability and Consequences)

Once the list of possible hazards has been assembled, the next action is to profile or characterize each hazard for probability and effect or consequence.

Probability

This is an assessment of the likelihood of the hazard or emergency occurring and is often described as improbable, low, medium, or high. Other related factors that may be helpful in assessing or describing probability include⁴:

- **Frequency of occurrence:** The more frequent the occurrence, the higher the likelihood.
- **Location of the hazardous event and the region affected:** Events that occur within or proximal to the community are more likely to affect the community, whereas events that occur at some distance may be less likely to affect the community.
- **Seasonal (or other cyclical) variations:** Events that occur with some regularity may be presumed to be more probable. Commonplace examples include the occurrence of "influenza season" each fall through winter and drought and/or floods (location-dependent) associated with El Niño.

Some hazards, such as civil disorder and terrorism, are by their nature highly unpredictable and may be difficult to properly assign a probability level.

Consequences

This is the effect of the hazard on the community and may be categorized into human, property, and business. Examples of each category include, but are not limited to:

- **Human impact**
 - Injuries
 - Illnesses
 - Fatalities
 - Psychological impact

- **Property damage**
 - Damage to or loss of use of buildings, structures, or domiciles
 - Damage to or loss of use of infrastructure (e.g., roadways, utility distribution systems)
- **Business loss**
 - Business interruption (including recordkeeping issues arising from loss of records, inability to access, compromise of integrity)
 - Unanticipated costs
 - Loss of revenue (from all causes such as loss of tourism, sales tax revenue, and fees for services)
 - Decline in property values
 - Adverse publicity
 - Fines, penalties, and legal costs

The degree of impact may be expressed qualitatively as nonexistent, low, medium, high, or catastrophic, or it may be expressed quantitatively as a numerical score. As a consideration, the HVA team may wish to add greater weight to hazards that occur without warning (e.g., tornado strike).

SUMMARY

The end goal of a community HVA should be a listing of hazards facing the community. Depending on the needs of the emergency management or lead planning agency, this listing may or may not be prioritized. An example of Durham County's (N.C.) HVA, excerpted from the county's 2001 Emergency Operations Plan, is presented in Box 17-2.⁵

As mentioned earlier in this chapter, the HVA is the foundation for the community's integrated emergency management activities, such as creation of plans, preparedness activities, hazard mitigation programs, and recovery plan development.

BOX 17-2 EXAMPLE OF DURHAM COUNTY'S HVA PLAN

Durham County is exposed to many hazards, all of which have the potential to disrupt the community, cause damage, and create casualties. Potential hazards (natural, technological, and national security) are:

- a. Major Fires
- b. Floods/Dam Failure
- c. Tornadoes/Severe Thunderstorms
- d. Severe Winter Storms
- e. Hurricanes
- f. Power Failure
- g. Drought
- h. Earthquake
- i. Mass Casualty/Fatality
- j. Hazardous Material
- k. Fixed Nuclear Facility (Ingestion pathway)
- l. National Security Emergency
- m. Civil Disorder
- n. Sabotage/Terrorism
- o. Aircraft Crash (Civilian/Military)
- p. Severe Bridge Damage
- q. Public Utility Damage (Phone, Electricity, Water, Sewer, etc.)

Threat Assessments

A subset of the community HVA that is receiving increased emphasis is the terrorism-specific vulnerability assessment (or threat assessment) tool.

Although a threat assessment appears similar to a community HVA in format and process, the threat assessment differs in several ways. For example, the threat assessment focuses only on the effects of malicious activities or persons on the community (versus all hazards). More sophisticated threat assessments actually look at the consequences of these malicious acts on specific targets, such as infrastructure, critical function areas, symbolic targets, or even special events (e.g., concerts). Threat assessments also are typically performed by law enforcement officials (versus a multidisciplinary team).

An excellent discussion of the terrorism vulnerability assessment process is provided in *Risk Management Series: Reference Manual to Mitigate Potential Terrorist Attacks Against Buildings*.⁶ Other good examples of terrorism threat assessments are the North Carolina Department of Agriculture & Consumer Services' Terrorism Threat Vulnerability Self Assessment Tool⁷ and the Pennsylvania Municipal Police Officer's Education and Training Commission's Vulnerability Assessment Worksheet.⁸

CONCLUSION

The HVA is a critical step for any community's emergency management activities. It is the HVA that methodically defines the scope and breadth of hazards that may be encountered in the community. Under CEM, hazards identified (and prioritized) by the HVA team will be addressed through a variety of means, including the development of emergency operations and response plans, hazard mitigation programs, and preparedness efforts such as training and drills. Although it is not possible to plan or prepare for every conceivable emergency, the HVA can ensure that plans are developed to deal with higher probability hazards or those with more significant consequences.

A special type of HVA, the threat assessment, focuses on the threat from terrorism or other malicious acts. There are even more specialized versions of these threat assessments that focus on specific utilities, industries, or operations. For example, RAM-W (or Risk Assessment Methodology—Water) is a threat assessment tool developed by Sandia Laboratories that focuses on the terrorism threat to potable water treatment plants.⁹

Healthcare facilities can both contribute to and benefit from the community HVA effort. Hospital administrators and experts may provide expertise to community emergency managers on issues such as mass casualty management, infectious disease consequences, and surge management. At the same time, the community HVA may be used as a basis for external hazards in the healthcare facility's own HVA. For example, if the community HVA identifies mass casualties arising from a hazardous materials event as a probability, this should be reflected

in the healthcare facility's HVA. Ultimately, it should be the goal of both community and healthcare facility emergency planners to have a coordinated response to all likely hazards.

Health Care Facility Hazard and Vulnerability Analysis

James C. Chang, William Gluckman, and Eric S. Weinstein

In 1988 Jan deBoer and colleagues¹ published the first attempt to mathematically score and classify a disaster to be used prospectively during the management of the calamity. A disaster was defined as “a destructive event that caused so many casualties that extraordinary mobilization of medical services was necessary.”¹ In the proposed Medical Severity Index of Disasters, the parameters needed to quantify a disaster were the casualty load (number of casualties), the severity of incident (severity of injuries sustained), and the capacity of medical services.¹ Seventeen years later, the importance of determining the impact of a disaster on a healthcare facility (HCF) has heightened because HCFs have become industrial leaders in the community and therefore must be able to swiftly return to normal business functioning. Individual healthcare providers are acutely aware of the business side of their practice while at the bedside, but they are not cognizant of the ramifications that a disruption of normal HCF operations would have on the community. Business and industry emergency management principles for HCFs to accommodate the clinical impact of a disaster are discussed in this chapter.

Disasters are events that cause significant enough damage to disrupt the normal activities or function of a community and overwhelm the local resources. What may be an easily handled event in a large urban city may be a disaster for a rural town. Although disasters are not predictable with any great accuracy, many consequences of disasters can be anticipated as part of a comprehensive emergency management plan that includes a hazard and vulnerability analysis (HVA). The HVA will help HCFs plan for these events and allow them to continue operating while assessing structural and operational damage, acquiring needed essentials, and protecting staff and patients. Much can be learned from business and industry with respect to preparedness.

Although not a new concept in business and industry, an HVA is a component in the development of a hospital disaster plan, as recognized since 2001 by the Joint Commission on Accreditation of Healthcare Organizations (JCAHO). The emergency management standard (EC.4.1) requires hospitals to identify specific procedures in response to a variety of disasters based on an HVA per-

formed by the organization.² The HVA will assist in the mitigation and preparedness of the HCF to respond to and then recover from a disaster. A hazard can be any threat that could cause injury; fatality; property, infrastructure, or environmental damage; or impair operations. An HVA is a tool used by emergency management to screen for risk and plan for strategic use of potentially limited resources.

HISTORICAL PERSPECTIVE

Many events have affected HCFs in the past. The future is certain to exhibit challenges as we move into a more technologically advanced society challenged by geopolitical terrorist threats. Hospitals inherently have to be prepared for emergencies. Preparation traditionally was based on informal HVAs and largely dependent on perceived issues. For example, hospitals in northern climates typically planned for adverse winter weather related issues; hospitals in the South planned for hurricanes; and hospitals in Southern California planned for forest and wild land fires and earthquakes. Failure to consider all hazards when developing the facility emergency response plan was a flaw in the informal approach.

Hazard identification relies on the collection of potential emergencies that the HCF or operation could anticipate encountering. This list may be assembled by cause, by location, or by a combination of both criteria. Causes may be divided into the following categories for assessment purposes: naturally derived emergencies, technologically derived emergencies, and manmade emergencies (Box 18-1).

HCFs experience two types of disasters: (1) those internal to the HCF, isolated to the confines of the HCF physical plant, and (2) those occurring external to the HCF that produce direct effects (casualties) and indirect effects (e.g., loss of electricity, supply due to damaged roads). The more common internal disasters are similar to those encountered by business and industry and until recently were not formally considered in an HVA. Milsten's³ exhaustive review of direct and indirect disasters that hospitals faced from 1977 to March 1997 showed that external and internal disasters are not mutually exclusive.

BOX 18-1 HAZARD IDENTIFICATION

Natural Events

Drought
Earthquake
Flood
Hurricane (cyclone, typhoon)
Landslide
Severe thunderstorm
Temperature extremes
Tidal wave
Tornado
Wildland fires
Windstorm
Snow/ice storms/blizzard
Volcanic ash
Meteor crashes
Infestation

Technological Events

Aircraft crash
 Medical evacuation helicopter
 Other aviation crash
Loss of medical gases
 Air
 Oxygen
 Nitrogen
 Nitrous oxide
Electrical/power shortage or failure
 Loss of backup generator(s)
Fire: chemical, paper, wood, other
Computer network disruption or loss
Loss of fire alarm, smoke detection
Loss of steam
Food contamination
Pneumatic tube disruption or loss
Food supply interruption
Loss or leak of potable water
Fixed facilities incidents
Loss of suction/vacuum
Loss of fuel oil supply or delivery
Elevator service disruption or loss
Hazardous material release
Structural failure
Natural gas/pipeline disruption
 Noxious fumes
Sewer failure
HVAC failure
 Loss of equipment requiring cooling
 Patient/staff at risk
 Loss of instrumentation (thermostat control/regulation)
Supply chain interruption
Labor dispute
Shortage of labor
Communication failure
 Paging: internal, external
 Emergency medical services or other radio
 Internal HCF telephone
 External telephone
 Cellular phone
 Satellite
Transportation disruption
 Labor dispute
 Roadway/highway incident/blockage

Human Events: With or Without Political, Terrorist, or Criminal Intent

Mass casualty incidents
Trauma
Civil disturbance
CBRNE*
Infectious disease
Foodborne illness

BOX 18-1 HAZARD IDENTIFICATION—cont'd

Abduction (infant, child, or adult)
Armed or threatening intruder
Bomb threat
Civil disorder
Forensic admissions
Hostage situation
Violent labor action
VIP visitor
Workplace violence

*Chemical, biological, radiological, nuclear, or high-yield explosive.

This chapter focuses on the HVA for events specific for internal disasters or those that directly occur within the confines of the HCF or indirectly affect the HCF due to consequences of the disaster.

CURRENT PRACTICE

Successful mitigation efforts and effective response plans are based on the best possible knowledge of the HCF's vulnerability in terms of deficiencies in its capacity to provide services, physical weaknesses, and organizational shortcomings in responding to emergencies. The HVA should also highlight and identify strengths within personnel, processes, plans, and other attributes. Past successes during disasters should be revisited to learn best practices, even if these occurred spontaneously due to inventiveness, teamwork, and a strong spirit to succeed.

All HVAs have some degree of subjectivity in their findings because many assumptions are made with regard to the perceived risk and even the level of preparedness if hard data are not available. Use of a multidisciplinary team should be encouraged to ensure a holistic characterization of each hazard and to help minimize the inherent subjectivity of the analysis and skewed or erroneous results. The team should be led by someone familiar with the HVA process and consist of representatives from at least the following areas within the HCF:

- Emergency management
- Security/safety
- Facilities (e.g., engineering, maintenance, information technology, telecommunications)
- Operations (e.g., nursing, medical staff, laboratory, radiology)
- Ancillary services (e.g., materials, food, housekeeping or environmental services)
- Administration
- Finance/business

Community representatives, such as the local emergency manager, fire official, police official, and city manager, can also provide valuable input. Additional members, including the hospital administrator-at-large may be beneficial as long as the group size remains manageable and consensus is achievable within a reasonable amount of time.

Regularly scheduled meetings with a defined agenda and other business-related models will assist the completion and maintenance of the assignment of the HVA team.

Most HVA tools come preloaded with a listing of likely hazards that the developer believes the average HCF could face. It is important that the HVA team begin by reviewing the listing of hazards in the HVA tool to ensure that it is applicable to the facility(s) and comprehensive. The HVA tool should address all possible events regardless of their likelihood. The first step is to “brainstorm” and determine all possible hazards, which can be accomplished with assistance from the county Local Emergency Planning Committee (LEPC) in conjunction with the Office of Emergency Management for both the county and state. The hazards are then classified into categories, as described in Box 18-1.

Risk, or impact, relates to the threat a particular hazard has with respect to the human impact: safety of people (patients and staff); property impact: structure(s) and property; and business impact: the ability to continue operations. Each risk can be assigned a numerical value to allow for a comparison or relative risk. The three types of impacts are averaged, and a score is assigned for each category. This will be important in the overall assessment.

Examples of each category include but are not limited to:⁴

- **Human Impact**
 - Potential for injury or death to staff members
 - Potential for injury or death to visitors
 - Potential for injury, death, or adverse outcomes to patients
- **Property Impact**
 - Damage to the facility (up to and including loss of the facility)
 - Loss of use of the facility
 - Loss of or damage to equipment and/or supplies
 - Costs associated with replacement/repair of the facility, equipment, or services
- **Business Impact**
 - Business interruption
 - Unanticipated costs
 - Loss of revenue (from all causes)
 - Recordkeeping issues (e.g., loss of records, inability to access, compromise of integrity)
 - Employees unable or unwilling to report for work
 - Patients unable to reach the facility
 - Damage to reputation
 - Fines, penalties, and legal costs
 - Future insurance premium increases

The degree of risk may be expressed as a numerical score or verbally with use of terms such as *nonexistent, low, medium, high, and catastrophic*. As a consideration, the HVA team may wish to add greater weight to hazards that occur without warning (e.g., tornado strike).

Probability relates to how likely an event is to occur at the facility or affect the facility, based on proximity. This, too, can be assigned a numerical value and is best determined from historical data (e.g., a scale of 1 to 5, with 1 representing a low probability of occurrence and 5 a very high probability of occurrence). Looking back

at historical data is critical in making an “educated guess” about the future. This is an assessment of the likelihood of a hazard or emergency occurring and is often described as *improbable, low, medium, or high*. Other related factors that may be helpful in assessing or describing probability include the following⁵:

Frequency of occurrence: Obviously, the more frequent the occurrence, the higher the likelihood.

Location of the hazardous event and the region affected: Events that occur proximal to the health-care facility are more likely to directly (or indirectly) affect the facility, whereas events that occur at some distance may be less likely to affect the HCF.

Seasonal (or other cyclic) variations: Events that occur with some regularity may be presumed to be more probable. Commonplace examples include the occurrence of “influenza season” each fall through the winter and drought and/or floods (location-dependent) associated with El Niño.

Where possible, probability should be based on objective data such as historical archives to learn of local disasters. Equipment failure rates or mean time between failure data should be available to the HVA team. Even maintenance records and expected length of service of equipment may lead to objective data that influence an HVA. Often, however, probability assessments are colored by the prior experiences of HVA team members and recent organizational memory.

Facility preparedness may be expressed explicitly in a separate category or integrated with another element (probability or risk). Intuitively, if the facility is well prepared to deal with an emergency, the impact of the emergency should be lessened. The presence of a preparedness component aids in tracking the organization’s preparedness efforts and is a means to decrement HVA scores as preparedness levels increase. Preparedness also should be reported to help determine the need for improvement in areas that have high risk and/or probability. Preparedness may be assigned a numerical value, or it simply may be a listing of what, if any, plans currently exist to address that particular event. It may also represent *resources* and the amount of them available (e.g., a lot, little, or none); resources can be subdivided into internal and external resources. The average of these two is the numerical value for preparedness.

Adding the numerical values of these three components (risk, probability, and preparedness) provides a value. Graphically looking at probability versus impact (Fig. 18-1), one would expect higher sums for those events that fall in the high probability-high impact areas and lower values for those events in the low probability-low impact areas.

For maximum benefit, the HVA should generate a prioritized listing of hazards with sufficient detail to characterize each one. To do this, a means to grade or rank each hazard, vulnerability, risk (consequence), and preparedness level should be considered. This characterization may be qualitative or quantitative; each approach has pros and cons.

Qualitative assessments may be simpler and faster to perform; however, these are often more difficult to fully

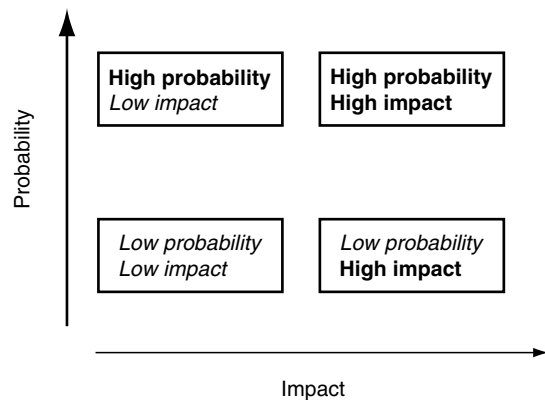

FIGURE 18-1. Probability versus impact.

implement in the end. A qualitative analysis may be as simple as having HVA members team rank-order a listing of potential hazards based on their subjective judgment. A slightly more involved approach to qualitative assessment is found in the HVA model provided by the Emergency Management Strategic Healthcare Group (EMSHG) of the Veterans Health Administration. This model uses a scoring system from 0 (not applicable) to 3 (high) for probability and risk (consequence). Any hazard with a score of 2 or greater in either category requires action.⁶ Qualitative HVA models often generate little differentiation between hazards and tend to group all hazards into one category (such as “high”) or another. These models have little flexibility in implementation and do not help the organization when it is time to determine organizational priorities for emergency planning and/or allocation of resources.

Quantitative assessments can be used to provide additional flexibility in implementation by enhancing the differences between each hazard. Depending on the HVA tool chosen, the scores for each hazard may be the sum or product of probability, risk, and preparedness scores or may be derived from more complex weighting schemes. For example, the HVA model used by Duke University Hospital (Durham, N.C.) takes the sum of the products of the probability of a hazard multiplied by the risk to people, property, and business, and then multiplies the resulting product by a facility preparedness score.

$$\Sigma (\text{Probability of Each Event} \times \text{Risk of Each Event}) \times \text{Facility Preparedness Score} = \text{Weighted Score of Event}$$

See Table 18-1 for an example of the Duke University Hospital HVA.

The end result of the Duke University Hospital and similar quantitative HVA models is weighted scores that address the probability, consequences, and preparedness level of each hazard. The weighted score of the event is then used to order its priority for emergency planning purposes. An institution may choose to address potential emergencies beginning with the highest-scoring event and progress down the list until all potential events are addressed. A variation of this theme may be to address the top five (or other number) high-scoring

events in year one, and presuming completion of planning, preparedness, and/or mitigation activities, address the next five-highest scoring events in year two and so on. A third alternative may be to establish a predefined threshold level; any hazard scenario exceeding this threshold value would require some type of action (i.e., planning, preparedness, mitigation).

Some more sophisticated HVA tools, such as the one developed by the Kaiser Permanente healthcare system, take the quantitative approach one step further by generating scores (percentages) and a graphical/visual output product.⁷

The HVA is the foundation for the organization’s emergency management program. It is therefore advantageous to expend the effort and resources to ensure that the job is done properly. The assessors should begin by developing a list of potential emergencies that the organization may face and then characterize each hazard as to its probability and consequence. An automated HVA tool is a significant time saver both as a means to test different scenarios for each hazard and as a documentation aid. Often a quick review of actual disasters, internal and external, that the HCF faced over the past 5 to 10 years is sufficient to commence action by the HVA team.

A systematic and consistent approach is needed. The team leader should ensure that all team members have equal input into the process.

The end product of the HVA should be a prioritized, all-encompassing, objective (to the extent possible) assessment of the possible, potential, or historical internal and external indirect events that may affect the HCF. The HVA produced is the foundation of the HCF’s emergency management program. It is used as the basis for planning and budgeting for hazard mitigation, preparedness, and response efforts within the institution. It should be intuitive that emergencies with the highest scores or ranks should be addressed first and lesser items handled as time and funding permit.

An annual review and revalidation of the HVA should be performed to ensure that changes to the operating environment of the facility are assessed for their impact on the facility’s emergency management program. Another reason for periodically reassessing the HVA is to reflect the benefit of hazard mitigation and preparedness activities. For example, as hospital preparedness activities reduce the risk (and consequences) of an emergency, such as a power failure, the item may be moved down on the list of priorities and other more pressing items may be moved up.

As a final consideration, the HVA work product (including drafts and working papers) should be considered a sensitive document and protected to the same degree as a patient record or a peer review, quality assurance/improvement, or sensitive business document. Remember that the HVA details the organization’s vulnerabilities, and depending on the format used and level of supporting documentation maintained, may describe how the facility will respond to an emergency. In the wrong hands, this information may actually increase a facility’s vulnerability to attack, and for this reason, it should not be freely disseminated (e.g., placed on the Internet). PITFALLS

A typical pitfall is underestimating the time required to develop an HVA and not allowing sufficient time to adequately complete the evaluation. In a large facility in a complex urban environment, an HVA may be a multiday process. A related pitfall is the gradual decline in interest as the evaluation progresses; the amount of time spent on each topic is typically directly related to how long the team has been working. Most assessments begin with an extremely thorough discussion of hazards and decline rapidly to more cursory examinations as the day progresses.

It is sometimes necessary to reiterate the sole purpose of the HVA—that is, the development of a prioritized listing of hazards to be addressed in the hospital's emergency planning process. It is not uncommon for representatives of a particular service or group to consider any mention of a hazard in their area as a personal affront. Care should be taken to ensure that this bias does not cause hazards to be arbitrarily dismissed with an "it'll never happen here" attitude.

HVAs are important in a well-designed disaster plan and thus need to be updated on a regular basis.

Geographic and industrial changes will affect a hospital and need to be considered. The establishment of a new chemical company in town, for instance, may make a significant change in an institution's assessment of hazardous materials threat.

Another problem, sometimes referred to as the "paper plan syndrome," gives the illusion of true preparedness simply because a written document exists. "Disaster planning is an illusion unless: It is based on valid assumptions about human behavior, incorporates an inter-organizational perspective, is tied to resources, and is known and accepted by the participants."⁹

CONCLUSION

In today's resource-constrained healthcare environment, it is not realistic to plan for every conceivable hazard or eventuality that may befall the institution. Healthcare administrators need to allocate their limited resources to ensure that likely scenarios are addressed promptly, whereas the "one-in-a-million" occurrences may be held in abeyance until some later date. The HVA is a tool for HCF administrators to systematically assess and characterize the plethora of hazards that their facility may face. Failure to exercise due diligence when conducting the HVA may have adverse consequences, ranging from professional embarrassment on the part of the emergency

management coordinator to loss of life, business interruption, damage to reputation, and litigation from inadequate emergency planning. Proper use of the HVA helps minimize these risks.

Public Information Management

Sharon Dilling, William Gluckman, Marc S. Rosenthal, and Eric S. Weinstein

In the chaos and craziness that ensues during or immediately after a disaster, whether it is a suspected contagious disease, an earthquake, or the explosion of a dirty bomb, there will be two constants: (1) the public will demand information about what is happening and (2) the media will be at the scene trying to tell them. Ever since images from Vietnam broadcast live into the living rooms of millions of Americans, the public has come to see breaking news coverage not only as a given, but as their *right*. The thirst for information grows with every passing minute, fueled by the ever-increasing competition within the media for advertising, sponsorship, and viewers. All of this factors heavily into disaster response. Balancing emergency care for the sick or injured with the need to disseminate accurate public information is always a challenge. Emergency responders would never think of treating a patient without having the proper medical training. Training for disaster communication is also highly important—preparation is the key. Understanding what types of information the public and the media will want and need will help mitigate the effects of the disaster, win the confidence of the media, and reassure the public. Information presented in a clear and truthful manner within a reasonable amount of time will further its effectiveness.

MEDIA HISTORY

The development of the printing press in the 15th century allowed inexpensively produced newspapers and books to spread information to large numbers of people.¹ When Marconi sent a wireless message in 1896, radio came alive, allowing electronic communication during World War I.² The newsreel brought edited pictures of World War II to moviegoers, albeit somewhat delayed. In the 1950s the “American dream” turned out to be a television as the centerpiece of every living room. By the 1960s, nearly all of America tuned in to watch the son of President John Fitzgerald Kennedy salute the flag-draped coffin of his father. Walter Cronkite became “the most trusted man in America.” And, of course, there was the Vietnam War. Television coverage has arguably changed the course of history by providing a window into the harsh realities of war that had never been seen before by most of America.

By the late 20th century, new media outlets developed, offering 24-hour-a-day news coverage, as cable television proliferated America. A few years later, as a new millennium approached, the Internet and e-mail revolutionized communication, allowing information to travel rapidly right to the desktop. This, coupled with the competitive news business, created even more demand by both the public and the media for up-to-the-minute communication. This urgency for information has surpassed accuracy and even, in some cases, reason. In 1994, millions tuned in to watch a white Ford Bronco with O.J. Simpson inside drive down a freeway. And then there was Sept. 11, 2001. The television images could not be edited to shelter viewers. They unfolded in real time, with real heartache. The world watched again and again with the hope of somehow hitting the pause button to allow the victims an additional moment or two of peaceful existence. Viewers tuned in for days, hoping to see people emerge alive from the burning rubble. News coverage was 24 hours a day for almost two weeks. Regular programming was preempted, and viewers struggled to come to terms with what had happened. As sad as it was, this horrific tragedy is a good example of what is expected of emergency response and public information.

MEDIA AND DISASTERS

The medical management of disasters, both small and large, requires a multifaceted response to ensure timely evacuation, assessment, treatment, and recovery. This response, usually based on the Incident Command System (ICS), requires the appointment of an incident commander, a logistics chief, and others. One important and often overlooked component of the ICS and disaster management in general is an area defined as *public information management*. The ability to provide appropriate, timely information can significantly affect the disaster response.

The components of public information management include not only the release of information to prepare rescue workers and volunteers, but the dynamic ongoing release of information to the media and the incorporation of the media within the response mission. Effective interaction with the media can improve the accurate

distribution of information that ultimately aids the response, while at the same time satisfying the needs of the media to “get the story.” This applies not only to hospitals or other institutions providing support in a disaster, but also to the rapid response elements (e.g., police, fire, and emergency medical services [EMS]) and to intermediate response organizations, such as the National Disaster Medical System’s disaster medical assistance teams, the U.S. Department of Health and Human Services’ Medical Reserve Corps, and the Federal Emergency Management Agency, to name a few.

During a disaster, potentially significant amounts of information should be communicated to the region affected to achieve a good response. This information provides the basis for management of the disaster as well as development of the public trust in the responsible agencies. For example, if a government frequently notifies the population of potential storms and their need to evacuate immediately, and subsequently, each storm causes insignificant damage, the population will learn to not trust the local government. If a category 5 hurricane then heads to this same region, the population may not heed requests to evacuate because they have been misled many times before and may not believe the local government or disaster coordinators. However, if the local government warns residents of only potentially dangerous storms and only requests evacuation for events that most likely will cause significant damage and injuries, while providing the details behind its decisions, the population will more likely respond to an evacuation request and, therefore, injuries and loss of life will be reduced. Obviously, the decision to warn or request evacuations is not just dependent on actual risks, but also on potential legal action or bad publicity should the disaster be worse than expected.

Further, immediately after an event, those who evacuated or had interests in the area will want to access the affected area to find family members, recover personal items, and assess the damage so that they may start to rebuild or repair. They will depend on information provided by functioning public communications systems. If this recovery action by those affected is not coordinated in a timely manner, people returning to the affected area can hamper appropriate response efforts and hinder response communications. For example, cellular phone towers may become overloaded with users and, therefore, important phone calls are not able to be placed. Providing re-entry instructions contained in the evacuation order and subsequent evacuation instructions is the best strategy. Phone numbers, radio stations, Web sites, and other means to provide timely and accurate information to those returning to an evacuated area will reduce anxiety, potential traffic jams, and the overuse of the limited resources of response agencies that will have to divert their focus to communication to an uninformed population searching for information. Finally, information about sources of food, potable water, medical care, cash, shelters and housing, fuel, and available government assistance needs to be communicated to the residents returning to the affected area.

Effective management of information can help minimize property loss and reduce the chance of injuries, even deaths, but also can improve the effectiveness of

response teams. To do this, methods need to be developed to communicate information to the population from one reliable, consistent source. Disasters do not just include the typical natural occurrence (e.g., flooding, hurricane, tornado) or manmade acts (e.g., industrial accident or terrorism) but also include loss of infrastructure (e.g., computer information systems, power grids, potable water, sewers, job action). Even though a disaster may not result in any injuries or fatalities, the fact that “something” went wrong brings the problem into the public eye. In such cases, the news media become interested and so do the government and public. The handling of the incident by the “offending” corporation or entity (1) can provide for a good public relations (PR) review and minimize the PR effect of the disaster, or (2) if poor PR ensues, can make the disaster more significant and potentially harm the corporation.

CURRENT PRACTICES

When a disaster strikes, media flood into the area. Be prepared to share your space. As word of the planes crashing into the two World Trade Center towers and the Pentagon spread, firefighters, police, and rescuers rushed to the scene. Not far behind were reporters, photographers, and camera crews. Tune into the local television station near where a hurricane is headed and undoubtedly reporters donning bright yellow rain slickers will be broadcasting from an evacuated beachfront while waves crash around them and lightning lights up the seas. Turn on the radio to hear broadcasters coughing out their report as the smoke of a nearby wildfire burns brush just steps away. Pick up a newspaper to learn how a reporter interviewed a family as they crouched in a storm cellar with a tornado blowing overhead.

Accepting media presence at events is important. Reporters will not go away, so it is best to help them find their way to a place that is close enough to the action to satisfy their needs, yet far enough away to prevent them from broadening the crisis by becoming a victim, or worse, placing emergency personnel at risk. When the media shift into crisis mode, they will broadcast whatever information they have in the order in which they receive it.³ Providing factual information to the media will allow one to effectively control the information instead of the information being in control. Reporters may or may not have time to verify the information, but they would rather report something than have nothing to report. If they have nothing to report, they probably will speculate. When the *New York Post* went to press with its July 6, 2004, headline, “Kerry’s Choice,” they declared Dick Gephardt as presidential candidate John Kerry’s running mate. Kerry announced his choice of John Edwards for vice president that same morning. The debacle mirrored the infamous 1948 *Chicago Daily Tribune* headline, “Dewey Defeats Truman.” In the Gephardt case, the already tarnished reputation of the *Post* took a hit, and the Kerry campaign benefited from the exposure.⁴ Although a mistake by the media can hardly be deemed a crisis, it clearly illustrates the pressure that time and competition weigh on the media. In

most instances, it is best to offer some information, even a small amount, to the media as long as it is correct.

Provide the media with factual information as soon as possible; even small or minor details or known truths can be helpful. The first source often becomes the most credible. Also, remember to demonstrate empathy when providing information.⁵ In the immediate aftermath of the destruction of the World Trade Center towers, New York City Mayor Rudy Giuliani spoke to the people of New York and the nation. He provided very little new information, but he told what he knew and demonstrated empathy—that he was grieving, too. “The number of casualties,” he said, “will be more than any of us can bear.”⁶ This was not an unknown fact, and it most certainly was not a new piece of information. Giuliani had never been known for his compassion, and his behavior after the World Trade Center disaster was a turning point in his career, making him arguably the most popular mayor in the city’s history.

Be honest. The truth almost always comes out anyway. There are numerous instances throughout history in which an initially dishonest action was forgiven by the public after the truth was told. If one shares inaccurate information and later the information is determined to be false, all credibility will be lost.

Time and space in the media are money. When a newspaper is put together, the first pieces to go in are the advertisements. Articles fill in the spaces around them. Space is at a premium. Select words wisely. Studies have shown that the average level of reading comprehension is at grade 6. If the message is targeted to a sixth-grader, the majority of the population will understand it; however, keep the audience in mind and adjust accordingly. For television, the rule of 27/9/3 is extremely helpful. Developed by Dr. Vincent Covello of the Center for Risk Communication, this rule suggests keeping messages to 27 words, 9 seconds, and 3 ideas or concepts for maximum comprehension.⁷

Media may not always be a friend, but they do not have to be an enemy.³ The media have a job to do, just like those who respond to a disaster. The media may play an essential role in communicating to the public during a disaster situation by offering evacuation routes, safety tips, or other important advice. Keeping the media up-to-date in an emergency is essential and should not be overlooked. Failure to provide frequent updates may result in the media using any means to get closer to the scene to get the information firsthand or going to possibly less-reliable sources. Make the media a friend, and let them relay the information you provide, as opposed to what someone else provides.

“Hope for the best but prepare for the worst” is a very applicable cliché concerning the need to have prepared public information systems in place before a disaster. Current practice for emergency preparation is to plan and drill response. This should always include testing the public information component.⁸

Medical/EMS/Fire Models

Disasters occur frequently, ranging from bus accidents with 10 to 20 injured persons, to hazardous material

events requiring local evacuation, to regional incidents such as hurricanes. In all of these cases, the local community or larger region enters a disaster mode as the resources needed are greater than one segment can provide. EMS must redirect ambulances and rescue vehicles, hospital emergency departments must prepare for casualties, and government provides resources for scene control and forensic investigation, with preservation of evidence balanced with response and recovery. All of this must occur while the daily standard delivery of healthcare and maintenance of law and order are maintained and the community infrastructure is preserved. The totality of the response is dependent on the size of the disaster and the numbers affected with the dynamic match of available resources, supplies, and the specific demands.

Many events happen simultaneously during the early stages of a disaster response: EMS/fire/police personnel are dispatched to the event and use an incident management system. Bystanders render aid, or as the word spreads, people arrive who may be able to help, but more than likely, they are not suitable responders. Plans should be made for this convergent volunteerism because it cannot be avoided (this is explored in other chapters of this text).⁹ Local emergency management representatives should work with local media to prevent a situation in which the media take it upon themselves to call emergency responders for help before the responders get direction from their office. If the media are asked to communicate a call for help, specific emergency personnel, upon arrival to the disaster scene, can then be directed to a gathering place and then directed to their duty station. Management of volunteers can consume precious resources away from critical aspects of a timely response. By reporting certain types of information, the media can fulfill an important role in assisting healthcare providers travel to their workplace, ensuring that any response teams are directed to their pre-arranged muster stations, and helping in prevention of injuries to unnecessary volunteers. The media responding to an event must also be directed to a location that enables them to accurately report while being kept safe.

In addition, it must be recognized that each response unit from various government and nongovernment agencies will have differing perspectives based on their interpretation of the dynamics of the event guiding their management or role. Unfortunately, all these views can diverge and provide a confusing and inconsistent picture of events, simply due to each unit’s perspective and underlying knowledge base. Caution must follow because each unit or members of each unit may be approached separately by members of the media and innocently provide inconsistent information. This can lead to misperception and loss of public trust. Further, if such misperception is acted upon by members of the command and control system, this may lead to disruption of the disaster response. Such misinformation may be a direct consequence of the real-time reporting that often occurs around disaster scenes. With media at the scene reporting in real time but missing vital elements or reporting unsubstantiated information, decisions can be rendered that can interfere with the dynamic response and recovery or divert resources, triggered by political expediency or a microphone held in someone’s face under bright lights.

Effect of Media Reports

A new area of media interaction related to disaster medicine is how the public responds to news reports and images that have the potential to induce posttraumatic stress disorder (PTSD).¹⁰ It has been reported that there is increased incidence of PTSD with intense coverage of an event, especially one associated with many images. This was reported to be especially true with the pediatric population.¹¹ The authors believe that intense exposure to significant events, such as the World Trade Center disaster, is associated with psychopathology.¹²

Media Communication

Several studies have looked at the public's response to uncertainty. These results can have implications on how the public will respond to media communications. One study found that a majority of respondents prefer ranges of risk estimates because they believe that these ranges makes the government look more honest. However, about half just want to know whether an area is safe or unsafe. Finally, disagreement among scientists about risk, even if a majority has one opinion, tends to result in the public assuming the worst. The implications of this reinforce the need for one spokesperson for a disaster response.¹³ Other studies looking at risk communication have provided goals for risk communication that could also apply to disaster communication, especially before the event. These are building trust, raising awareness, education, agreement, and motivating action. Before a hurricane or another major disaster, the development of these goals will help foster action by the community. The media become the vehicle for the communication of these goals and needs to work with the public information officer (PIO) and responsible organization to develop them.¹⁴

Detroit Free Press Example

The media are also concerned with safety and minimizing interference with the relief effort. The *Detroit Free Press* requests that their reporters and photographers work as teams. These teams are allowed to do whatever is needed to get a story as long as they feel comfortable or safe, obviously a very large leeway for the reporter. The teams are expected to be as inconspicuous as possible and to identify themselves to responsible agencies, including the police, to reduce potential problems. Reporters and their editors want to publish information that they believe is accurate, timely, and has been verified with multiple sources, if possible. They prefer to verify information with at least two, but preferably three, sources. In addition, they have deadlines that must be met. Finally, these teams are willing to help responsible agencies to disseminate information as long as they have access (T. Fladung, managing editor, *Detroit Free Press*, private communication, 2004).

Lessons from Recent Disasters

Multiple disasters have occurred within the last 10 to 15 years that provide a glimpse into the *do's* and *don'ts* of

public information management. These events have stemmed from airplane and train disasters, earthquakes, and terrorist actions. In each case, lessons learned have improved disaster response and have shown the importance of public information management.

Tokyo Sarin Attack, 1995

On March 20, 1995, Tokyo experienced a nerve gas poisoning attack with sarin. The first patient from this attack arrived at the hospital before ambulances began delivering patients. Approximately 2.5 hours after the event, the first press conference was held at one hospital, and the first televised news announcement was made 3 hours after the attack. At this point, most patients had reported to a local medical facility. In addition, there was no initial report to the population from an official source until after all patients had left the scene. In this case, the media notification and distribution of information from an official were late, but the information after the initial conference was consistent.¹⁵

Oklahoma City Bombing, 1995

On April 19, 1995, a terrorist action caused an explosion that destroyed the Murrah Federal Building in Oklahoma City. The blast was felt by many in the local area and was reported by news networks very quickly. The local emergency departments (EDs) immediately became fully staffed; many medical personnel immediately offered their services to local EDs, and as the departments became staffed, personnel decided to go directly to the explosion site and provide freelance medical care and rescue efforts. In addition to the local response, the local media, without notification or request, directed those with medical training to go to the federal building to provide care. This resulted in more than 300 volunteers at the site. Even though volunteers provided evacuation assistance, the site was unsafe and the responders did not have protective gear; as a result, one volunteer died from falling debris.¹⁶

Some of the lessons learned from this disaster included how to request that additional healthcare providers go to their respective facilities and how to prevent untrained and superfluous volunteers from converging on the scene. If the need for additional support arises at the incident location, the incident management commander can request this through emergency management channels. The media can then receive a specific request for specific volunteers to be directed to a gathering, muster, or staging area for credentialing, briefing, equipping, and transportation assignments. The receiving medical facilities can then, either by direct communication or preexisting disaster protocols, have their requests met through proper channels and be prepared for the additional healthcare professionals, limiting resources dedicated to incorporate them into the existing staff. The media should be informed early in a disaster of set expectations of their role, any boundaries placed on them, and how they could potentially hinder the response and recovery. This partnership should be communicated to the public to build public trust. In

addition, if the incident management team does not want bystanders because of safety concerns, this should also be conveyed to the media so that they might communicate this information to the public.

PITFALLS OF MANAGING PUBLIC INFORMATION

Managing the flow of information in a crisis or disaster is no small task. There are, however, 10 common pitfalls to be avoided.

Failing to Bring in Experts

Emergency responders are supposed to respond to emergencies: physicians are supposed to take care of sick or injured patients, search and rescue teams are called in to look for trapped individuals, and firefighters battle fires. When a disaster occurs, be it large or small, an expert who can speak about it effectively should be summoned.

This is not to say that a firefighter is not the best spokesperson at the scene; it means that anyone speaking to the media, or formally to the public, should have some basic public information officer training.³ In a large-scale disaster, it is strongly recommended to have a designated key spokesperson. There are training programs available through the Centers for Disease Control and Prevention, the Federal Emergency Management Agency, and a number of private companies that specialize in crisis and risk communication.

Avoid Using Complex Language or Jargon¹⁷

In a crisis situation, the listening skills of people involved are highly challenged. They often do not hear correctly, are overcome with emotion, and are experiencing high anxiety. Additionally, audiences in a crisis may vary in their level of education and comprehension. A best practice guideline is to target communications to the reading level of a sixth-grader.¹⁷ Try to keep information clear, succinct, and to the point. Do not use acronyms or abbreviations because they may confuse the public.

Avoid Arguing, Fighting, or Losing Your Temper

Disasters by nature are stressful. It is difficult to remain calm when dealing with situations that involve extensive loss of life or property. Often, disaster workers go without proper rest for long periods, and it is easy for tempers to flare. When speaking to the public or a reporter, remaining calm is the key. Do not be afraid to politely end a conversation if it becomes heated or uncomfortable. Reporters almost always win an argument; they have the editor on their side. Offer a succinct and truthful

response for best results, and stay on your message.⁸ Repeat your main idea as many times as necessary. Do not deviate from your main message or key points.

Do Not Predict

Often, questions about what will happen next will be asked after a crisis. Unless one arrives on-scene with a working crystal ball, these kinds of questions should not be answered. No one can predict the future. Reassure the public that every effort is being made to mitigate the crisis or that the best possible care is being offered.¹⁸

It Is OK to Say, “I Don’t Know”

Do not answer a question that you are not qualified to answer. In fact, when offering information to the public, be prepared to repeat the information you do know several times in several different ways. Admitting you are not qualified to answer a specific question and suggesting someone who can may even add to your credibility.⁷

Failing to Show Empathy

Empathy or sensitivity is essential in disaster communication. Whereas many first responders or healthcare providers often emotionally detach themselves from a crisis situation, public information officers cannot. The most effective communicator is one who cares.⁷

Lying, Clouding the Truth, or Covering Up

History has shown us, from Watergate to the Monica Lewinsky scandal to the legal woes of Martha Stewart, that it is often not the initial incident that is the problem, but rather the cover-up. Never cover up or hide information. In this day and age of e-mail, cellular phones, and up-to-the-minute communication, the information is almost always going to get out. Of course, discretion and good judgment are factors, but avoid lying or blatant cover-ups.

Not Responding Quickly

Slow and steady do not win the race in a disaster response, be it rescuing the injured or communicating the issues.¹⁸ Respond quickly and thoughtfully. Also, be sure to be accurate and truthful.

Not Responding at All

The infamous words “no comment” bring chills to experienced PIOs everywhere. There is almost always something better to say than “no comment.” Some suggestions include, “I don’t know,” or “I’ll get back to you with an answer to that question.” The main thing to remember when tempted to respond with “no comment” is that this refrain instantly makes the speaker sound as if something is being hidden or there is something dishonest about what is happening. Always remember what can be commented on and offer that instead, even if it does not answer what the reporter asked.

Failing to Practice Emergency Communications

Schools practice fire drills. Communities practice evacuations. Hospitals drill for emergency response. Communications should be an essential part of any drill. Practice is the key to success when a real disaster hits. Allow the information officer to participate in scheduled exercises, and ask local media to attend. Work with them in advance so that they may provide a more realistic scenario with the stresses that come along with the reporting of a major event.⁸

The key to managing public information is to be prepared, respond quickly with accurate information, and show empathy.

CONCLUSION

Good disaster management provides for a mass communication system with appropriate information. The goal of this system is to establish relationships between the response agencies, the media, and the public. A major underpinning for success is accurate and timely information to the public.¹⁹ The media can be a friend or foe. Mutual respect for each other will generally result in better cooperation and a smoother interaction. The provision of timely and accurate information will help keep reporters from searching for unreliable facts. The media most likely will not be the cause of any panic. Any panic by the population will be based on the incident, not the reporting of it.²⁰ It is recommended for organizations that may have to deal with the media to have a media policy in place before an event. In addition, a representative or PIO is needed on-site. The media also do not just want facts, but human interest stories. Establish procedures to allow responders to tell their story: highlight outstanding efforts or acts of heroism and then notify the media.²¹ PIOs should consider predeveloped news release forms and develop a contact list for the area and a list of "experts" to call on to explain the situation to the public and reporters.²² Even though the media can be intrusive, they also can disseminate accurate information as well as advice or warnings.²³ Recommend that the media assist in providing accurate information to the public. Before events, have the media participate in disaster drills and network with organization leaders for disaster events.²⁴

Informatics and Telecommunications in Disaster

Churton Budd

The United States and many other countries are facing the threat of a number of new crises as the result of terrorist activities. Behind them looms the ever-present danger of a natural disaster, such as an earthquake, fire, or hurricane, and manmade or technological disasters, such as a transportation accident or loss of an electrical grid. All of these incidents generate strong demands on the collection, analysis, coordination, distribution, and interpretation of many types of health and preparedness information. Along with the increasing risk of bioterrorism, there is a greater requirement and stronger emphasis on the use of sophisticated information-gathering tools and information technologies to accomplish. These tools are necessary to manage the complex surveillance needs and the data analysis necessary to spot trends and make early identification of outbreaks, as well as allow for rapid communication of health information, mitigation strategies, and treatment modalities to healthcare workers in the field.

Fortunately, many of those involved in emergency management have begun to embrace technology, and consequently, many vendors have recognized the need to produce hardware and software to meet the needs of disaster responders. Various tools have been used to help mitigate, prepare for, and respond to disasters. One of the more difficult issues during a response to a disaster is the inability to communicate. The breakdown of communications has been a recognized effect of almost every major response to a disaster. Communications issues occur at some level in almost every disaster response, no matter how large or small. As the disaster community has experienced these failing communications systems, it has found strategies to improve the systems or replace them with methods that work. Over time, the ability to accumulate, analyze, and disseminate disaster preparedness and response information has improved. Largely, this is due to advances in information technology that have taken place during the past half century.

HISTORICAL PERSPECTIVE¹

The disaster response community got off to a slow start with embracing information technology; however, this

technology is rapidly gaining momentum. In the past, before the 1980s, computer systems were primarily used in the business, banking, and scientific communities. For the most part, anything close to emergency or disaster planning use of these systems was limited to the Department of Defense and large commercial research firms who did operation planning and simulation, or occasionally, epidemiological or sociological studies.

During the 1980s, the desktop, or personal computer (PC), was introduced. Data could be stored on a disk that was easily carried in a briefcase. By the mid-1980s, disaster responders could enter data into a computer so that documents could be produced, spreadsheets updated, and commodities and resources tracked, sometimes even in the field. During the late 1980s, the Internet began to gain popularity and became more in the reach of the average person. The precursors to the Internet—BITNET and ARPANET—transformed into the World Wide Web, and at that time the average citizen began getting a dial-up Internet connection via CompuServe or America Online. Online resources at major centers of learning began to accumulate databases related to disaster management and planning. People could exchange files and documents via e-mail or by way of a number of sites that acted as file repositories, called FTP sites (for file transfer protocol—the methodology of transferring binary and text files from one computer to another). Special software programs called “gophers” (short for “go for this and that”) cataloged these file repositories and allowed a person to search for them by keyword. These programs were the precursor to the big search engines such as Yahoo and Google.

Applications such as CAMEO (computer-aided management of emergency operations) were developed in 1988 by the National Oceanic and Atmospheric Administration. CAMEO is used to assist first responders with easy access to response information. It provides a tool to enter local information and develop incident scenarios. It contains mapping, an air dispersal model, chemical databases, and other tools to help display to the emergency responder critical information in a timely fashion. Hazardous materials information and material safety data sheets (MSDS) became available on CD-ROM.

Other databases also became available on CD-ROM to allow the responder access to a library of information while at the disaster site. About this time, the Centers for Disease Control and Prevention (CDC) released Epi Info (www.cdc.gov/epiinfo). Using this software, an epidemiologist or public health professional could develop a questionnaire or form, customize the data entry process, and enter and analyze data. Epi Info can be used to produce epidemiological statistics, tables, graphs, and maps.

Specialized computer mapping software called geospatial information systems (GIS) integrates data with map information. Because disasters are usually spatial events, GIS can assist in all phases of disaster management. It is often easier for disaster planners to see a map of the disaster to assist in plan development. A map will show the scope of the disaster, where damage is greatest or has the greatest impact, what property or lives are at risk, and what resources are available and where are they needed. Disaster managers, using GIS to graphically display critical information that is location-based, can quickly map the disaster scene, establish priorities, and develop action plans.

In the 1990s, information exchange improved exponentially. List servers on the Internet allowed emergency managers, disaster responders, and medical providers the ability to discuss disaster response in an informal setting. It was not uncommon to see a post to a list server from a responder actually at the site of the disaster. Lessons learned could be immediately disseminated throughout the disaster response community. Agencies such as the Federal Emergency Management Agency, the Natural Hazards Center at the University of Colorado, and the CDC all began to publish large amounts of public information about disasters on their Web sites. The use of satellite telephone systems and cellular phone-based data networks allowed those with a laptop to stay connected in the field and collect and transmit a large amount of information to other responders and to their response agencies.

Today, it is hard to find someone in the disaster response field that has not used e-mail or some type of computer resource to do his or her job. It appears that the use of information technology is reducing operational costs and increasing productivity, although this is difficult to quantify because information technology is still growing so rapidly. Portable computers have now decreased in size to as small as a handheld personal digital assistant (PDA). The cellular phone and PDA have merged into a communications/information device. Although still falling behind that of the corporate sector, information technology training for disaster response and management personnel is beginning to be a job requirement. Electronic commerce is allowing disaster responders to achieve real-time procurement and payment for relief supplies. Broadband and wireless networks can be set up rapidly and cheaply to allow for access to vast informational resources. The public has become far better educated, and they seek information on their own health-care; manage their finances online; and now are able to research, mitigate, and prepare for disasters using the many publicly available resources on the Internet.

What does the future hold for informatics in disaster management? It is hard to tell because information technology in general continues to develop so quickly. It is more than likely that the disaster responder will one day use a wearable computer with a small flexible screen. It is also probable that voice and data technologies will continue to merge so that interaction with digital devices can be accomplished by voice command. Storage devices will continue to become smaller so that victims of a disaster may have their entire financial records, health records, and other personal information archived on a chip they carry in their pocket, which will allow them to save this important personal information from being destroyed by a disaster. Real-time monitoring and surveillance will assist the disaster responder to become aware of an impending disaster sooner. The ability to monitor patient flow, track resources, and perform real-time mapping and visualization of the disaster scene will allow planners and managers to “roll with the punches” during a disaster and modify the response effectively. It is likely that information technology will continue to be a stronger and stronger tool for disaster response personnel.

CURRENT PRACTICE

To help understand how informatics and telecommunications can assist during disasters, various tools and elements of informatics and communications that are currently being used by disaster managers and responders are discussed. Some of these tools are used in the preparation and mitigation stage, and some are used during the response phase. Some tools can be used in all phases of the disaster cycle.

Computer Devices

One can quickly realize that the computer has revolutionized many aspects of our lives. Some people are so dependent on e-mail for doing their daily work that when the corporate e-mail system goes down, they find it hard to conduct business. The same is true for researchers using the Internet and the vast amount of knowledge on the World Wide Web to do their research—when it is inaccessible, they almost feel withdrawal symptoms. There are many types of computer devices available to a disaster manager or responder—everything from corporate mainframes to wearable personal computers.

The Laptop

Probably the most commonly used device other than the desktop PC is the laptop. As technology improves, the speed and power of laptops are becoming close to that of a desktop. Because memory and storage are cheap, the average laptop has a larger hard drive than it did just a few years ago. Many of the applications written for the desktop are also used on the laptop, so many laptops have memory equivalent to that of the desktop. New chipsets and microprocessors use lower power and run cooler, allowing for longer running time on

batteries. Some laptops are even fanless, greatly improving battery life. Laptops are getting thinner, and many of them are bundled with all the accoutrements such as wide theater-like screens, DVD players, CD burners, and high-speed connections for peripheral devices such as fire wire and universal serial bus (USB) connectors. Most new laptops also include wireless access technologies, such as Bluetooth and WiFi. With a docking station and external keyboard, mouse, and monitor, many people are finding that they can use their laptop docked at their desk and then pop it out and take it when they travel. This takes the place of a desktop computer and provides the user all the amenities of the office or home while out in the field. See Box 20-1 for tips on traveling with a laptop.

The Tablet PC

Similar to a laptop is a specialized portable computer called a tablet PC. Only recently on the market but finding rapid popularity, these devices use primarily a pen input for data entry. Tablet PCs are finding a niche in vertical markets such as healthcare and on the warehouse floor. They can be extremely useful for filling out forms such as a medical record or a field survey at a disaster site that can be plugged into a GIS for mapping. Tablet PCs usually have equivalent performance to that of a laptop, with the added convenience of usually a

longer battery life, a slightly smaller form, and the pen-based input.

When selecting a laptop or tablet PC to take to the field, one will be deluged with hundreds of choices. In selecting a device, it is important to consider the conditions under which the device will be used. There are many “hardened” devices, specifically designed to military standards for shock and vibration resistance, water resistance, and dust impingement. These hardened PCs can be twice the price of the regular off-the-shelf laptop. If a hardened PC is affordable, one can rest assured that it will more than likely survive being taken into the field and be able to keep data safe. An alternative, however, is to purchase an off-the-shelf laptop from a local computer/electronics store and an insurance policy for it. Oftentimes, a \$50-per-year policy with a deductible of only a few hundred dollars is available. This would easily cover a catastrophic loss of the device (e.g., major drop, crush, or immersion), but it probably would not cover minor damage such as the disk drive door breaking off. When buying a hardened PC, one should ask the vendor specific questions about drop and immersion tests and whether the device meets Mil standards (Box 20-2).

If at all possible, test a device in various types of weather, from direct sun to night time. Make sure the screen is readable in direct sunlight, can be dimmed for use during night operations, and is ergonomic when held and does not cause undue strain due to weight or bulkiness. Try the doors, accessory ports, and plugs to make sure that by simply plugging a peripheral into the PC, it is not rendered immobile or unwieldy or that its water resistance or another hardened standard is not rendered ineffective.

BOX 20-1 CHECKLIST FOR TRAVELING WITH A LAPTOP

- Update the antivirus and spyware protection software to the latest virus definitions because one cannot be sure that a network used on the road is fully protected.
- Use a program, such as Norton Ghost, that can make a drive image, which creates an image of the laptop's hard drive, so that if the hard drive crashes, it can be recovered from the image.
- Check the batteries and if time permits, cycle them all the way down and back to full charge again. If possible, take an extra battery that is charged to extend your PC time if you are isolated without power. Consider alternative power sources, such as solar panel chargers, disposable battery replacements and power cells, and a 12-volt adapter for converting power from a car battery to use your laptop.
- Preparations for traveling with a laptop include placing the computer in a hard-shell padded case. It also helps to have an assortment of plugs and adapters and an extra network cable, just in case. Don't forget a power/recharge cable.
- Put everything in plastic baggies, even when the equipment is in its case. If you can find a large enough baggie for your laptop, you can protect it from moisture should your case be exposed to the elements and leak. Temperature changes can cause condensation, so if you do pack your equipment in baggies, throw a couple of silica gel desiccator packs into the baggie, too.
- If you know you will be in an area operating on generator power, take a surge protector to prevent power spikes from damaging your devices.
- At all costs, avoid having your laptop or computer device go through a baggage check—make sure it can be stowed as a carry-on. Try to keep it away from metal detectors because they might erase magnetic media.
- Take a cable lock so that you can secure your laptop somewhat. Although it won't prevent a thief who really wants it, it may deter someone walking by and snatching it while you have your back turned.

The Personal Digital Assistant

Another handheld device that is usually smaller than the tablet PC is the palm-sized personal digital assistant (PDA). The PDA has become the peripheral brain for many in the healthcare setting. Rather than wear or carry a laboratory coat full of plastic cards with scores and scales, quick guide books, and other reference texts, a healthcare provider can store all of this information in a PDA. The information can be indexed and referenced quickly. PDAs come in two types: the Palm Operating System and the Microsoft Pocket PC Operating System. Most of the major vendors are authoring software for both platforms, but the Palm platform has been around longer and has more shareware and freeware medical titles. A PDA can be an invaluable resource for the disaster responder. Often in the field, the disaster responder does not have the luxury of ducking into the

BOX 20-2 MIL-STD 810

MIL-STD is a series of specifications set by the U.S. Department of Defense. When purchasing a hardened device for field use, look for vendor affirmation that their device meets military standards to ensure that it will survive use in a post-disaster field environment.

emergency department library to look up something in the *Physicians Desk Reference* or another medical text. With a PDA, however, one can “take” those texts to the field (Box 20-3). In many cases, searches can be done with a keyword to rapidly find the needed information.

The address book, calendar, contacts, tasks, and notes are probably the more commonly used built-in applications on a PDA. Other uses of the PDA for disaster response include keeping track of contact information for other disaster responders and agencies. There are also a number of programs that allow for rapid form filling and database applications for recording data and creating quick ad-hoc reports. Some PDAs have built-in cameras, allowing one to rapidly document a disaster scene for later use. With accessories such as an external keyboard, one can even type full documents on the PDA and can print the documents with an infrared-capable printer.

Although PDAs may seem to be stand-alone devices, they require periodic visits to the laptop or desktop for synchronization. During this synchronization process, vendors provide updates to software over the Internet; calendars, address books, tasks, and notes are synchronized with desktop software; and new software can be installed from the desktop to the PDA. If you are recording data on forms on the PDA, this synchronization may also be required to pass the data from the forms tool on the PDA to an application running on the desktop as a full-featured database.

As with the laptop, there are a number of accessories that are useful to have when traveling. An attachable keyboard is helpful to type reports on the PDA for printing later. The PDA should have a hard-shell case, and it is advisable to pack the PDA in a plastic baggie for protection against the elements. With the PDA, hundreds of free medical texts and references available on the Internet can be accessed and would be quite useful if a disaster responder becomes isolated from reference resources. These can be found by searching the Internet for texts and software related to healthcare and disaster and response; some will be free, some will be for sale. A solar battery charger is ideal for a PDA because its batteries do not require much energy to charge. Lastly, make sure that data on the PDA are uploaded to a desktop or laptop computer, and try to store critical files and infor-

mation on the removable memory media. In the event that power is unavailable and the PDA loses its charge, all the data may be lost without that backup.²

Like the laptop or tablet PCA, a PDA comes with many choices. For those not familiar with a PDA, it is advisable to borrow one for a day, if possible, to get a feel for the work flow and how it would be used during a typical day. Pay attention to whether the device can fit into your pocket or whether you will have to carry it around in a case that you might put down and forget or not have on hand when you need it. The ideal device is small and unobtrusive; however, the device should have enough computing power, storage, and functionality to meet the user’s needs. One should also consider purchasing a hardened PDA. Although not expensive in comparison with a hardened laptop, a PDA that has been designed to take into the elements will still be twice the price of an off-the-shelf model. The small size and highly portable nature of the PDA may make it a better investment because the user may be more likely to take it into the field than a laptop.

Local Area Network/Wide Area Network/Wireless Network

As emergency managers are getting more sophisticated in their use of information technology, it is not uncommon to see disaster responders establish a local area network (LAN) where their incident command is set up (e.g., in the Emergency Operations Center or in the disaster field office). This network links a group of computers together and allows instant messaging between computers; the sharing of files and documents between computers; and, better yet, the centralization of file storage to one large networked hard drive that each workstation has rights to access. Thus, a backup can be taken of just that centralized hard drive periodically rather than each individual workstation. In many cases, a wide area network can be established, which is the linking of more than one LAN. For example, the disaster field office may be linked over a public network through a virtual private network (VPN) to the main office or headquarters. This VPN connection provides a secure tunnel through the Internet from point to point so that sites in between cannot access passing traffic. This creates a wide area network that is not limited by geography or distance, just connectivity.

Wireless networks are fairly new and take advantage of a network access point, which is a transceiver that communicates with a wireless transceiver card on the workstation or laptop. Essentially, this topography creates a wireless network similar to a wired one, but with the convenience of rapid setup without the need to string network cable all over the site. Wireless networks could even be deployed in a tent city, linking treatment areas in the tents to a command tent. Unfortunately, wireless networks, like voice radio frequencies, can be fairly easily received and decrypted by an eavesdropper, thus making them fairly insecure. Sophisticated encryption methods must be put into place to protect sensitive operational security and patient information that may be transferred across a wireless network.

BOX 20-3 USEFUL PDA PROGRAMS FOR DISASTER RESPONDERS

- Epocrates (www.epocrates.com): Enhanced drug and formula-ry reference with integrated ID treatment guides and tools.
- WISER (<http://wiser.nlm.nih.gov/>): WISER provides a wide range of information on hazardous substances, including substance identification support, physical characteristics, human health information, and containment and suppression advice.
- Skyscape Books (<http://www.skyscape.com>): This is a portfolio of medical references for use on handheld devices.
- PEPID (<http://www.pepid.com/>): PEPID is a physician, critical care, and nursing reference suite.
- Sites that have PDA medical software:

Communications Devices

Geographical Positioning System

The Geographical Positioning System (GPS) began as a military system in 1985 and is based on a 24-satellite configuration of transmitters. By measuring the distance to four satellites from the user location, it is possible to establish three coordinates of the user location (latitude, longitude, and altitude). Although originally developed for the Department of Defense, the not-quite-complete system was offered to the civilian community in 1983 by President Reagan after Korean Airlines flight 007 was shot down when it accidentally strayed into Soviet Union airspace. The satellite configuration was complete in the early 1990s, and the Gulf War prompted the sale of thousands of commercial GPS receivers; at that time the military had not manufactured many GPS receivers. Since then, GPS has found its way into the travel, surveying, mapping, and delivery industries. In addition, many casual users take a GPS when they are recreating in remote areas or to locate their favorite fishing spot. For the disaster responder, a GPS unit can be helpful in giving an exact location of a shelter or the location of a landing zone for helicopter evacuation and can assist in the location and mapping of resources to be used to respond to the disaster. There are a number of accessories that will convert a PC or PDA into a sophisticated GPS mapping unit.³

Cellular Phones

A cellular phone is probably the most common tool that people use to communicate. Many disaster response agencies consider the cellular phone to be their primary communications tool and issue them to their disaster responders. Consequently, cellular sites after a disaster may experience a high demand as the civilian population makes calls to friends and family to check on their welfare, as responders arrive and begin to arrange resources, as the media arrive and make arrangements to cover the story, and as people shift to cellular as their primary phone if their land line phone is inoperable because of a power outage or other disruption. It is reasonable to assume that a cellular phone may have difficulty in making a connection during a postdisaster response due to the cellular site being overwhelmed. Normally, cellular providers scale their cellular sites to handle only 20% to 30% of their customer base at a time. This is fine for normal traffic, but when a disaster strikes and customers all need to make a contact in a compressed time frame or when outside people come into the area with their cellular phones, the cellular sites may be congested into uselessness. Fortunately, a few initiatives are in place that might reduce this congestion on the cellular systems, especially for disaster responders. Cellular phone providers can deploy a trailer with a cellular antenna, repeater, and generator power, as well as a cell site on wheels (COW) that can be strategically placed in the disaster area and connected to the public telephone network to increase the availability of cellular connections. Also, a few cellular providers have enabled a capability in their systems in which an emergency worker can receive

priority on the cellular phone system and get a connection sooner. Unfortunately, there is no legal requirement for them to do so, and as a result of the expense of purchasing additional hardware to make this happen, only a few providers have adopted this technology. Most have not; therefore, this is not a reliable option. After the 2003 summer blackout, only one cellular phone provider in New York City provided priority access.⁴

Satellite Phone Systems

There are a number of satellite phone system providers that use a number of different technologies. IMARSAT is probably the oldest vendor of satellite phone service; it started its service in the early 1990s. The early phone systems consisted of a fold-out, umbrella-like antenna and a briefcase-sized box with a handset. They were portable, although bulky, and the transmission of data over the phone system, if possible, was done at very slow speeds of 300-4800 bits per second (compared with 700-1500 Kbits per second on a broadband cable modem). Satellite phone costs originally were as high as \$3 a minute, but most of the current vendors charge about \$1 per minute. Phone size also has shrunk to more the size of a laptop. The flip-up lid of the phone, similar to opening the screen of a laptop, acts as the antenna and should be pointed at an angle toward one of the satellites.

Because many of these phone systems use a geostationary orbiting satellite constellation, one must be geographically aware and point the antenna in the correct direction and at the correct inclination to get a good signal on the satellite. There are automatic antenna systems on a number of vendors' satellite phones, which can be mounted to a vehicle so that the phone can maintain a line of sight link to the satellite and be used during travel to the disaster site. Dense leaves or vegetation as well as very dense rain can reduce the signal strength. Some newer phone systems, such as Iridium and Globalstar, have a handset that is not much bigger than a cordless phone for home use. These systems use a constellation of low earth-orbiting satellites and incorporate the group special mobile (GSM) protocol for cellular phone technology, allowing the handset to connect to terrestrial GSM cellular networks while in signal range to a cellular site and then automatically switch to an orbiting satellite when out of the terrestrial GSM range. Unfortunately, satellite phone systems are very expensive to bring into service and maintain. A number of vendors have been close to bankruptcy and been saved by investors.⁵

Mobile Communications Vehicles

Many response agencies have built and deployed vehicles that are outfitted with communications and computer equipment that is capable of performing a variety of functions. These vehicles usually are equipped with their own generators for power and contain a number of different radio systems that can be programmed to communicate on many different radiofrequencies. A radio operator in the vehicle can pass information between disparate radio systems and agencies and may be able to help with some of the lack of interoperability issues. These vehicles also

have the ability to patch into a telephone network and the Internet. Depending on their sophistication, they may have satellite phone systems, high frequency radio, and facsimile capability computers with scanners and printers. Specially trained teams of radio operators, both amateur and public safety dispatchers, and information technology personnel usually staff one of these vehicles. Oftentimes, the incident command staff makes use of these vehicles as part of their command post, or the vehicle can support a disaster response team or disaster field office until more permanent communications can be set up. In events such as mass gatherings or disasters of limited duration, a communication vehicle such as this can be used to provide rapidly deployed communications support in a small footprint and then be completely disassembled at the end of the event.

Radio Systems

Whole books have been written on radio communications, even specifically on disaster communications. Professional communications specialists and many amateur radio operators have spent hundreds of hours training themselves on these systems, so this chapter only gives a mile-high view of the communications systems and frequencies that may be used during a disaster response. It is a good idea for the disaster responder to be aware of what systems are in use, when they should and should not be used, and how to best take advantage of these tools.

Radiofrequency (RF) is the part of the electromagnetic spectrum in which electromagnetic waves can be generated and fed through an antenna. There are a number of different modes of the RF spectrum that are most often used for voice and data transmission during a disaster response (Table 20-1). High frequency (HF) is the frequency range from 3-30 MHz and is classically termed “shortwave.” HF radio waves are often reflected off the ionosphere, thus frequencies in this range are often used for medium- to long-range terrestrial communications. Sunspot and other solar activity, polar aurora, sunlight/darkness at the transmitting and receiving station, and even the choice of frequency within the spectrum can diminish the relative difference between the signal strength over the background noise (signal-to-noise ratio) and make communication on HF radio unusable at times. In other words, if interference increases the static (noise), a transmitter must be more and more powerful to have the transmitted signal hearable above that noise. HF radio is used in some widely dispersed populations for domestic broadcasting. HF radio is often used for HF networks of radio operators who can, in short term, pass information from one radio station to another, essentially allowing, by a number of “hops,” worldwide communications. Amateur radio operators oftentimes provide the first information to the outside world when a disaster site is cut off after a hurricane or a major geological event.

For more local communications, very high frequency (VHF) may be used and ranges from 30-300 MHz. FM radio (88-108 MHz) and various television signals are included in this range. VHF is not usually reflected off the ionosphere so it is limited to local communications. VHF is not as affected as lower frequencies by atmos-

TABLE 20-1 TYPICAL RADIOFREQUENCIES USED IN DISASTER RESPONSE

BAND	FREQUENCY	DESCRIPTION	USES/LIMITATIONS
HF	3-30 MHz	High frequency	Good for long distance because the radio waves bounce off the ionosphere back to earth. Subject to environmental noise and interference.
VHF	30-300 MHz	Very high frequency	Line of sight, less affected by environmental noise. More easily blocked than HF by land features.
UHF	300-3000 MHz	Ultra high frequency	Line of sight, better penetration of land and manmade features. Smaller wave size allows for smaller antennas.
SHF	3-30 GHz	Super high frequency (microwaves)	Passes more easily through the atmosphere and terrestrial features than VHF and UHF. More radio spectrum available in this band.

pheric noise and interference from electromagnetic sources; it does, however, penetrate buildings and other substantial objects more than higher frequencies. Ultra high frequency (UHF) includes frequencies from 300 MHz to 3 GHz. UHF also includes some frequencies dedicated for television signals (in the United States, above channel 13). UHF frequencies penetrate some densely built buildings a little better than VHF frequencies do. UHF wavelengths are very small, allowing for more compact antennas, which some people feel are more convenient and more attractive than the longer VHF antennas. In more sophisticated communications systems, there may occasionally be a super high frequency (SHF) signal, which includes microwaves transmitted from one antenna in line of sight to another. These SHF microwave signals can carry voice and data. Satellite radio bands are contained within this range of frequencies.

With a two-way radio, there are two types of uses of the frequencies. Simplex use of a frequency means that the same frequency is being used to transmit and receive; while one person is talking, nobody else can talk. Duplex use of the frequencies allows duplex conversations, like on a telephone. Additionally, duplex frequency use can allow for a repeater to be placed centrally in the disaster area. The repeater receives on one frequency and rebroadcasts out at higher power on the other frequency. The repeater is usually put in a high location or has a high antenna. Repeater antennas have a high gain, meaning they can pull in weak signals and strong transmitters that can transmit signals farther. A repeater allows the transmission of handheld radios to be extended from just a few miles to tens of miles. Frequencies that do not penetrate buildings well, such as UHFs, have better transmission.⁶

Specialized Informatics Systems and Decision Support Tools

In recent years, the need for specialized information systems composed of databases, surveillance tools, personnel and patient tracking, and evidence-based medicine to support disaster response and management have been recognized. Health departments, which in many cases did not operate 24-hours a day, seven days a week and in some situations did not even have fax capability 10 years ago, now are developing and putting into place sophisticated systems to monitor for bioterrorism, emerging diseases, and ecological impact on a population.

The television cable network CNN is often at the disaster scene rapidly passing on information. This was the case Sept. 11, 2001, when millions of people witnessed the second plane hitting the World Trade Center as broadcasters were on the air covering the event in minutes. Field personnel can send hundreds of e-mails a day from the disaster site back to their agency. Resources come into play faster as response plans gear up and agencies and their personnel begin reporting back their status. There are many ways to communicate, and the amount of information available to decision makers has increased and is dispersed more rapidly. Information can come into the local response center and at agency headquarters oftentimes directly from the source. Each piece of information must be interpreted and requires a familiarity with the source. Assessments, requirements, and needs from the field may come in from many different sources, each with possibly contradictory information. Oftentimes, this can only be correctly interpreted by the local incident commander. In a wide-area disaster, this may be very difficult to consolidate and evaluate at a higher level.

The analysis of the information coming in from field responders is as important as the information flow itself. Consolidation in a meaningful manner and then appropriate communication to the headquarters should be done by someone knowledgeable enough at the local level to pass only that consolidated information gathered by their support personnel. Many examples exist of these types of decision support systems. The CDC makes its decisions based on information consolidated from state health departments. State health departments make their reports to the CDC based on information passed on by local health departments, who, in turn, received their information from the emergency department physician who, for example, may have noticed six patients with the same abnormal symptoms in the last hour. If that emergency physician were to call the CDC directly, the information would be documented but may not account for much until the physician had passed the information through the correct channel for consolidation and communication to a higher level.⁷

Humanitarian Information Systems

Humanitarian information systems (HIS) are specialized systems linking many sources of information and consolidating and reporting them. HIS consists of an early warning and reporting system, which includes the monitoring of specific trends of values, such as rainfall

amounts, vegetation mapping, crop production, and market prices, and measures of human factors, such as nutritional status, unemployment, and poverty level. In a smaller-scale disaster, this could include a severity score tabulated from a door-by-door outreach effort to rate the occupants of a dwelling on a number of health, psychosocial, and life safety scores and then map those using a GPS location and a GIS to plot the overall postdisaster health and safety of the community. Thus, a needs assessment is conducted to estimate the needs of the affected population. An HIS should track the resources on hand and the delivery of those resources and then gauge whether the resources are meeting their goals and being delivered to the victims in an efficient manner.⁸

Surveillance and Bioterrorism Detection Systems

Whereas an HIS is a mix of various pieces of software integrated into a single system, bioterrorism detection systems are being developed with federal funds and by private corporations that include continuous surveillance of hospital data from a number of sources. This allows for normalizing and analysis of that data for statistically significant patterns and less specific indicators and rapidly alerting health officials of a developing trend. In the recent past, public health surveillance did not occur in real time, but that has changed and data must begin to be collected often before cases are confirmed and cultures are reported positive. Often there is a narrow window of opportunity after an exposure in which treatment is most effective, such as for anthrax, and rapid identification of similar symptoms from multiple sources can be facilitated if a surveillance system is in place, where real-time reporting can take place. As technology improves, environmental biosensors can be linked to the system to provide even earlier detection before widespread infection and symptoms occur. As most hospital information systems register every patient, de-identification can be done on patient data and the reason for visits can be easily transferred to a local database and even to a national database such as the National Electronic Disease Surveillance System advocated by the CDC. It is more likely that the initial detection of a covert biological or chemical attack will occur at a local level. More and more local and state health agencies are developing ways to detect unusual patterns of disease and injury. Early response to such patterns is essential for ensuring a prompt response to a biological or chemical attack. Unfortunately, many of these projects are at a regional or state level. Local and even some state health agencies budgets are still meager, and the cost of research and development of these systems is still out of reach for many smaller municipalities. If a system is developed, it usually lacks integration with other information systems and often relies on a person to do the daily initial data load or complex schemes of transmitting the data between systems. The Department of Defense system, ESSENCE, which downloads outpatient data from almost 300 Army, Navy, Air Force, and Coast Guard installations around the world each day currently receives the data in one to three days of patient visits, longer than ideal for an optimal reaction to a potential outbreak. Systems that rely

on a person interpreting patient visits for key indicators and inputting them into a central database are prone to variations and interpretation of how the data should be tabulated and entered, creating room for error and inconsistency. Furthermore, it has been demonstrated that early detection of just hours can make an enormous difference in a covert attack. Unfortunately, prototype automated surveillance systems have never been able to prove that they can detect a pathogen that quickly and may render a false sense of security. There are very few vendors of bioterrorism surveillance software. Currently the most promising endeavors are those funded by grants from the Department of Defense, CDC, and other federal agencies.³

SUMMARY

Disaster informatics and telecommunications have become indispensable tools for disaster managers and responders. As pervasive as these tools are in our daily lives, they are finding their way more and more into the field. E-mail, instant messaging, LANs and intranets, cellular phones, two-way radios, teleconferencing, and many other sophisticated tools are becoming common in handheld devices and in the pockets of disaster responders. Information is a commodity, and the ability to analyze and distribute it to aid in the reduction of human suffering is probably the best money spent.

Device selection will probably be the disaster responder's most difficult task because there are thousands of brands on the market for desktops, laptops, tablet PCs, and PDAs. Vendors may be of help in selecting a product that meets the user's needs, but many vendors are not familiar with the disaster responder's role and may not understand what "punishment" the device may endure. Generally, vendors who sell hardware that is being used in the public safety and field service fields will have a better idea of the harsh environments in which the equipment will have to operate. These vendors are a good first choice to talk with about the different devices.

Protecting the device and data is the next important task for the technologically armed disaster responder. Making sure that the device is stored in a padded, hard shell case for shipping and travel and ensuring that there are redundant backups of the data at multiple points in the preparation, deployment, and demobilization phases are important. This includes taking backup copies of software on a CD in the event that the hardware is damaged in the field.

GPS receivers, cellular phones, radio systems, and the Internet are all tools that a disaster responder may use during a response to help establish and maintain communications with the home agency and other responders. These tools will be a lifeline for ongoing support and the reporting of events. Again, the user will be faced with trying to determine the best radiofrequencies to use for any given circumstance. The disaster responder will need to locate the best vendor for cellular service near the disaster area—one that's large enough or has a large enough customer base that it is in the vendor's best financial interest to supplement local or damaged cellu-

lar stations to ensure better usability of the system after the event. Having multiple options for Internet access, such as dial-up, wireless, and fixed LAN ability, will ensure the user flexibility in plugging into whatever is available after a disaster.

As the disaster responder becomes more reliant on electronic equipment for postdisaster duties, he or she will need to consider alternative power sources and methods of recharging batteries, such as solar chargers, hand generators, and disposable power packs. He or she will need to consider taking any number of wall chargers, cords, dongles, adapters, and plugs to the disaster site. The electronic and communications demands for rapid information and assessment in the response and recovery efforts of a disaster mission will prompt the disaster responder to become more computer savvy, more electronically aware, and more technically knowledgeable, and as a result, the disaster responder will be more productive. Reports and assessments must be rapidly tabulated and disseminated through the chain of command. Assessment efforts may rely on computerized surveillance techniques, information gathering and database development for resource tracking, and statistical analysis—all with the ability to rapidly communicate this information to various players and agencies at the disaster site in an organized and succinct manner. As pervasive as each of these technologies is getting in our daily lives, it is obvious that they are becoming equally so in our role in disaster response.

Disaster Mitigation

Robert M. Gougelet

The definition of *mitigation* includes a wide variety of measures taken before an event occurs that will prevent illness, injury, and death and limit the loss of property. Mitigation planning commonly includes the following areas:

- The ability to maintain function
- Building design
- Locating buildings outside of hazard zones (e.g., flood plains)
- Essential building utilities
- Protection of building contents
- Insurance
- Public education
- Surveillance
- Warning
- Evacuation

It is of critical importance that emergency planners incorporate the basic elements of mitigation and have the authority and resources to incorporate these changes into their organization/facility/community. Emergency planners should have a basic idea of the concepts of mitigation through their use in natural disasters over the years. The recent federally mandated transition to the all-hazards approach in disaster emergency response has also given a new perspective on mitigation. Although it is not necessary to redefine mitigation, it is essential to understand how the scope and complexity of mitigation and risk reduction strategies have evolved as the United States adapts to new threats. For example, what measures can be taken in advance to protect the population and infrastructure from an earthquake, flood, ice storm, or terrorist attack? As with each mass casualty event, the answers to this question are location-specific and heavily dependent on the circumstances surrounding the event. However, a common understanding of the goals and concepts of mitigation along with knowledge of its policy history and current practices will help a community develop mitigation plans that are both locally effective and economically sustainable. This chapter illustrates how mitigation strategies have evolved, outlines key historical elements of U.S. mitigation policy, highlights critical current mitigation practices, and describes common pitfalls that can hamper mitigation efforts. The realm of mitigation planning is

far reaching and complex, and, therefore, the emphasis of this chapter is on the continuity of medical care during a mass casualty event within a community.

GOALS AND CONCEPTS OF MITIGATION

In the simplest of terms, mitigation means to lessen the possibility that a mass casualty event can cause harm to people or property. However, this simple definition covers a broad range of possible activities. For example, an effort to ensure that essential utilities, such as electricity and phone service, continue to be available throughout a natural disaster is very different from efforts to minimize the economic damage of postdisaster recovery from a major flood or attempts to educate the public on how to reduce their risk of exposure during a dirty-bomb incident.

Mitigation strategies can range from focusing exclusively on “hardening” to focusing more on resiliency. Hardening of targets is best described as measures that are taken to physically protect a facility, such as bolting down equipment, securing power and communications lines, installing backup generators, placing blast walls, or physically locking down and securing a facility. Mitigation through hardening has only limited use in systems or facilities such as hospitals where open access to the surrounding community is the hallmark of their operations. In these circumstances, a resilient system capable of flexing to accommodate damage and the ability to maintain or even expand current operations will make that system ultimately more secure. Mitigation through resiliency also has limitations. In many cases, hardening structures is most appropriate, particularly when many citizens may be quickly affected without prior notice or warning. This may include hardening structures in earthquake zones, physically protecting and monitoring the food chain and drinking water systems, and physically securing and protecting nuclear power plants. In these cases, resiliency may come too late to prevent illness and death in large numbers of patients, and planners should target hardening to whatever degree is practically and financially feasible. The threats of nuclear, radiological, chemical, and biological attacks present new challenges for emergency planners. The potentially covert nature of

the attack, the wide variety of possible agents (including contagious agents), and soft civilian targets make planning efforts exponentially more difficult than in the past. This complexity has also eroded the distinction between mitigation and response activities. Although it is never possible to mitigate or to plan responses for all contingencies, we do know, however, that there is a basic common response framework. This framework includes coordination, communication to enable inter-agency information sharing,¹ and flexibility to rapidly adapt emergency plans to different situations.

RECENT HISTORICAL PERSPECTIVE

Traditionally, mitigation in the United States has focused on natural disasters; however, early mitigation planning against manmade disasters included civilian fallout shelters and the evacuation of target cities if a nuclear attack was eminent. The Federal Emergency Management Agency (FEMA) states²:

Mitigation is the cornerstone of emergency management. It's the ongoing effort to lessen the impact disasters have on people's lives and property through damage prevention and flood insurance. Through measures such as; zoning restrictions to prevent building in hazard zones (e.g. Flood plains, earthquake fault lines), engineering buildings and infrastructures to withstand earthquakes; and creating and enforcing effective building codes to protect property from floods, hurricanes and other natural hazards, the impact on lives and communities is lessened.

Mitigation begins with local communities assessing their risks from recurring problems and making a plan for creating solutions to these problems and reducing the vulnerability of their citizens and property to risk.³

However, since the mid-1990s, mitigation planning has become increasingly more complex. Terrorist attacks, industrial accidents, and new or reemerging infectious diseases are just a few of the threats that have started to consume more planning time and resources. The growing scope of threats that must be addressed in mitigation strategies challenges all aspects of planning and response at all levels of government.⁴⁻⁶ The importance of sharing intelligence information at the earliest possible stage of a terrorist attack, especially a bioterrorism event, is now recognized in national policy as a critical mitigation asset. Theoretically, if there were the slightest indication of a contagious biological attack occurring within the United States, then early recognition triggered by intelligence alerts followed by appropriate local responses could allow for isolation, treatment, and containment of a potentially widespread event. This intelligence sharing must become a large part of mitigation efforts aimed at limiting the effectiveness of manmade disasters. A similar analogy can be made with the early warning given to the medical community when a surveillance system picks up an unusual cluster of illnesses, long before the initial diagnosis may be made at a physician's office or healthcare facility. The new National Incident Management System (NIMS) states that intelligence must be shared within the incident management structure and states that a sixth functional area, or

Incident Command System Section, covering intelligence functions may be established during the time of an emergency. The elevated status of intelligence within NIMS establishes the importance of early and effective intelligence sharing. The challenge is to establish these sharing relationships before the disaster by incorporating them into an ongoing hazard monitoring process and by integrating them into drills, exercises, and day-to-day activities to ensure that this critical resource is operational when needed to mitigate the consequences of a disaster.⁷

The Disaster Mitigation Act of 2000 (DMA-2000) elevated the importance of mitigation planning within communities by authorizing the funding of certain mitigation programs and by involving the Office of the President. Under DMA-2000, the president may authorize funds to communities or states that have identified natural disasters within their borders and have demonstrated public-private natural disaster mitigation partnerships. DMA-2000 provides economic incentives through promoting awareness and education to prioritize the following objectives for federal assistance to states, local communities, and Indian tribes:

- Forming effective community-based partnerships for hazard mitigation purposes
- Implementing effective hazard mitigation measures that reduce the potential damage from natural disasters
- Ensuring continued functionality of critical services
- Leveraging additional nonfederal resources in meeting natural disaster resistance goals
- Making commitments to long-term hazard mitigation efforts to be applied to new and existing structures

This important legislation sought to identify and assess the risks to states and local governments (including Indian tribes) from natural disasters. The funding would be used to implement adequate measures to reduce losses from natural disasters and to ensure that the critical services and facilities of communities would continue to function after a natural disaster.⁸

Further evidence of the expanding complexity of mitigation efforts can be found in the Terrorism Insurance Risk Act of 2002. This act fills a gap within the insurance industry, which typically does not provide insurance coverage for large-scale terrorist events. The federal government, in the wake of the Sept. 11, 2001, attacks, promptly passed this act, addressing concerns about the potential widespread impact on the economy. The act provides a transparent shared public-private program that compensates insured losses as a result of acts of terrorism. The purpose is to "protect consumers by addressing market disruptions and ensure the continued widespread availability and affordability of property and casualty insurance for terrorism risk; and to allow for a transitional period for the private markets to stabilize, resume pricing of such insurance, and build capacity to absorb any future losses, while preserving State insurance regulation and consumer protections."^{9,10} Effective mitigation planning now is expected to include many different aspects of private industry. Private industry is a critical partner; its involvement may range from being a potential risk to the community, such as a chemical plant, to providing assistance in responding to an event. This is especially

true in the area of healthcare; most healthcare in the United States is provided by the private sector. It is important to note that the National Fire Protection Association (NFPA) recently released NFPA 1600, *Standard on Disaster/Emergency Management and Business Continuity Programs*, 2004 edition. This standard establishes a common set of criteria for disaster management, emergency management, and business continuity. Planners may use these criteria to assess or develop programs or to respond to and recover from a disaster.¹¹

Although mitigation planning has become an essential feature of nearly every industry and institution in the wake of Sept. 11, 2001, healthcare settings are disproportionately affected by new challenges and complexities in mitigation. The severe acute respiratory syndrome (SARS) outbreak shook the foundation of mitigation and prevention in healthcare when healthcare workers and first responders in China and Canada died in 2003 after caring for patients with the SARS virus. Access to several Toronto area hospitals was significantly limited for several months because of illness, quarantined staff, and concerns about contamination. The economic costs to the city of Toronto were in the billions of dollars. Hospitals and their communities were thrown into a complex mitigation and prevention crisis.

The Association of State and Health Officials (ASTHO) has come out with specific guidelines and checklists to help prepare states and communities prepare for a possible outbreak.¹² Pan-influenza planning closely parallels SARS planning, with considerable effort toward preventive vaccination of the population and emphasis on protecting healthcare workers.¹³ Effective strategies were learned during the Toronto SARS outbreak, although it was definitely a “learn-as-you-go-along” situation. The most effective mitigation strategies to prepare for the consequences of an outbreak would be to plan for the home quarantine of patients, establish public information strategies to reduce public concern, to close affected facilities until the knowledge base permitted their safe reopening, plan for a coordinated information and command and control center, and have preestablished protocols and procedures in place to protect the health of healthcare workers and first responders.¹⁴

Vaccination is an essential component of hospital and community mitigation planning. During the fall of 2002, the U.S. government requested that all states prepare for a smallpox attack. The preparations called for each state to present a plan within 10 days to vaccinate all persons within the state, starting with healthcare workers.¹⁵ Each facility and community needs to look at the risk of a disease, the effect of vaccination on healthcare workers, and the ability to maintain continuity of care. If properly informed, healthcare workers could respond and treat patients without risk to themselves or their families. The availability of a vaccination and the ability to mass vaccinate the majority of the population should be considered in all community response plans. The plans for both SARS and pan-influenza now need to address the availability and possible stockpiling of antiviral agents as well as procedures for mass vaccination of the population, if a vaccine were to become available.

We have learned much from the many earthquakes, tornadoes, hurricanes, fires, and floods that the United States has experienced, but it is extremely difficult to plan for terrorist and natural events that can quickly overwhelm communities, states, or even the whole nation. These historical events, policy developments, and shifts in public attention have created a very complex planning and operating environment. The next section of this chapter addresses some of the key current practices that mitigation strategists should consider.

CURRENT PRACTICE

Current mitigation strategies are as varied as the circumstances in which they are formed. This section illustrates the impact of mitigation through a comparison of responses to two earthquakes that were broadly separated in geography and community preparedness. These examples are followed by a discussion of critical elements of mitigation and risk reduction practice in three broad categories: coordination with other organizations and jurisdictions, hospital concerns, and mitigation strategies based in community health promotion and surveillance.

The first step for protecting communities and their critical facilities against earthquakes is a comprehensive risk assessment based on current seismic hazard mapping. This determination of location should also include the assessment of underlying soil conditions, the potential for landslide, and other potential hazards.¹⁵ Communities located on seismic fault lines must also develop and enforce strict building codes.

After the Bam, Iran, earthquake, a large section of the city, at first glance, looked like a burned forest with only the bare trees left standing. It soon became clear that these were steel vertical beams standing upright in mounds of concrete rubble. In comparison, after the Northridge, Calif., earthquake many of the buildings were structurally compromised but did not collapse on their occupants. Undoubtedly, this was the result of the strict building codes and enforcement throughout the state of California. To the victims of the Bam earthquake, the most important lifesaving measures may have been the development and enforcement of strict building codes.¹⁶ Building codes are minimum standards that protect people from injury and loss of life from structural collapse. They do not ensure that normal community functioning might continue after a significant event.¹⁷

Structural protection of facilities requires the active role of qualified and experienced structural engineers during planning, construction, remodeling, and retrofitting. The immediate response of a structural engineer after a disaster is to assess building damage and to assist in determining the need for evacuation and the measures needed to ensure continuity of function. Extensive analysis of seismic data taken during an earthquake that are compared with subsequent building damage has given structural engineers valuable information on structural failures of buildings. This information allows communities to rebuild with better and stronger facilities.¹⁸

The following measures to protect the structural integrity of a facility should be in place before an incident¹⁹:

- A contract with a structural engineering firm to participate in planning, construction, retrofitting, and remodeling
- A contractual agreement guaranteeing the response, after an event, of a structural engineer (with appropriate redundancy) to ensure structural stability, to assess the need for evacuation, and to take additional measures to ensure the continuity of essential functions
- Inventory and classify all buildings
- Conduct a vulnerability assessment
- Ensure code compliance
- Determine public safety risks
- Determine structural reinforcement needs, and prioritize them
- Prepare lists of vulnerable structures for use in evacuation and damage assessment

Extensive resources and technical assistance for structural earthquake protection are available on the Internet. FEMA's Web site itemizes these resources into three major categories: earthquake engineering research centers and National Earthquake Hazards Reduction Program-funded centers, earthquake engineering and architectural organizations, and codes and standards organizations.²⁰ FEMA has released the *Risk Management Series* publications, which provide very specific guidance to architects and engineers about protecting buildings against terrorist attacks.²¹ The Institute for Business and Home Safety is also an excellent source of incident-specific information for both businesses and homes.²²

The protection of facilities from earthquake damage also involves protecting the facility's nonstructural elements. These nonstructural elements do not comprise the fundamental structure of the building (Box 21-1).

Primary damage to nonstructural elements may be the result of overturning, swaying, sliding, falling, deforming, and internal vibration of sensitive instruments. Relatively simple measures, which do not require a structural engineer, may be taken to prevent damage to or from nonstructural elements. These measures may include fastening loose items and structures, anchoring top-heavy

items, tethering large equipment, or using spring mounts. Other elements, such as stabilizing a generator from vibration damage by placing it on spring mounts or from sliding damage by having slack in attached fuel and power lines, may require the assistance of an engineer. Hospitals and other medical care facilities are especially vulnerable to damage from nonstructural elements. Consider the placement of routine medical care items such as intravenous poles, monitors/defibrillators, and pharmaceutical agents and medical supplies on shelves. Loss of emergency power to key services, such as computed tomography scanners, laboratory equipment, and dialysis units, may also significantly affect the continuity of medical care (E. Aur der Heide, personal communication, February 2005).²³ Loss of generator power may be due to failure of crossover switches, loss of cooling, or loss of connection of power and fuels lines. A process for the continual review of the power needs of new and critical equipment should be a part of a hospital's emergency planning process.

Cooperating with the federal government and understanding the resources, structure, and timeframe in which the federal resources are available are critical to appropriate mitigation planning.²⁴ NIMS and the National Response Plan are described elsewhere in this book. Each document describes in detail the organizational structure and response authority of the federal government in the time of a disaster.^{25,26} Healthcare organizations, communities, and states are mandated to ensure that their strategies for mitigation, response, and recovery are developed in coordination with these national models. Presidential Decision Directive Homeland Security Presidential Directive (HSPD) #5 mandates that by fiscal year 2005, "the Secretary shall develop standards and guidelines for determining whether a State or Local entity has adopted the NIMS,"²⁷ and all mitigation and risk reductions strategies should be designed accordingly.

In addition to efforts to coordinate with federal plans, mitigation strategists must also build functional partnerships within communities and across jurisdictional lines. This point has been emphasized in several recently published planning guides.^{17,28-30} These guides help hospitals and their communities plan for mass casualty events by incorporating key features of planning, risk assessment, exercises, communications, and command and control issues into functional and operational programs.

Hospitals also present special challenges. Presidential Decision Directive HSPD #8 specifies that hospitals qualify as first responders.³¹ As such, they have important mitigation activities to consider. What does mitigation mean for a hospital? In the current threat environment, it means minimizing the impact of an event on the institution and ensuring continuity of care.

Accessibility to the public 24-hours a day, seven days a week has been a hallmark of hospital emergency care. However, one of the most important mitigation strategies a hospital can adopt is the ability to limit and control access to patients and families during the time of a mass casualty or a hazardous materials event. Additionally, facilities must have plans and the ability to decontaminate patients, protect essential staff and their families, handle a surge of patients with complimentary plans for

BOX 21-1 NONSTRUCTURAL ELEMENTS

- Cabinets
- Compressed gas tanks
- Fuel tanks
- Generators
- Equipment and supplies
- Signs and pictures
- Electrical lines
- Communication and information technology lines
- Bookshelves
- Windows
- Electrical fixtures
- Storage containers
- Hazardous materials
- Lockers
- Building parapets and facings
- Computer hard drives

the forward movement of patients to surrounding areas, set up alternative treatment facilities within the community, to train staff in early recognition and treatment of illness or injury related to weapons of mass destruction, and ensure continuity of care and financial stability during and after an event.

Although hospitals will always form the cornerstone for medical treatment of patients during mass casualty events, best practices for hospitals must now also incorporate healthcare resources within the community.³² Hospitals will have to work with other first responders within the community to conduct drills and exercises that realistically test the whole hospital's ability to respond to a mass casualty event.³³ Hospitals also will have to ensure that staff members have the proper training to complete hazard vulnerability assessments³⁴ and to set up and staff outpatient treatment facilities to ensure continuity of care.^{35,36} Even with very careful planning, most communities will be overwhelmed for the first minutes to hours or possibly days after a massive event, until an effective and prolonged response can occur. Communities must also look at the continuity of medical care as a communitywide issue and not just emphasize the hospital or emergency medical services aspects of medical care. The loss of community-based clinics, private medical offices, nursing homes, dialysis units, pharmacies, and visiting nurse services can significantly increase the number of patients seeking care at hospitals during a mass casualty event. Risk communication and education, specifically aimed at protecting the affected population, can help prevent surges of medical patients.¹

Hospitals now have enormous community responsibilities in terms of preparing for and mitigating mass casualty events. Hospitals in hurricane, flood, earthquake, and tornado zones have prepared for many years against these threats. However, a pattern of repeated systems failures within hospitals continues and includes communications and power loss, with additional physical damage to the facility.³⁷ To prevent such failures, hospitals need to recognize that mitigation and risk reduction planning must approach the level of detail and logistical support that parallels military planning.

Surveillance is another key mitigation strategy for health emergencies. Early recognition of sentinel cases in biological events can significantly affect the outcome, particularly in contagious events. States are funded and required to participate in the surveillance programs mandated in CDC and Health Resources and Services Administration guidelines.^{38,39} The earlier an event is recognized, especially if it involves a contagious disease, the earlier treatment can begin and preventive measures can be taken to prevent the spread of illness to healthcare workers and responders, as well as the rest of the community. Public health departments are critical to establishing relationships between local providers and their communities. Local, state, and federal public health agencies must ensure that effective surveillance at the community level occurs. These agencies can also assist in awareness-level and personal protection training for hospital staff, emergency medical service employees, and law enforcement first responders.

PITFALLS

Motivating healthcare facilities to take part in mitigation is one of the largest challenges in disaster medicine. It is always best to take measures beforehand to minimize property damage and prevent injury and death. In the case of hospitals, some preliminary research indicates that four factors affect an institution's motivation to mitigate: influence of legislation and regulation, economic considerations, the role of "champions" within the institution, and the impact of disasters and imminent threats on agenda-setting and policy making. It was discovered during this research that "mitigation measures were found to be most common when proactive mitigation measures were mandated by regulatory agencies and legislation."⁴⁰ Tax incentives, government assistance grants, and building code and insurance requirements may also serve to motivate administrators and decision makers to put the necessary time and effort into mitigation planning.¹⁷

CONCLUSION

Extensive mitigation activities are a necessary prerequisite for the response and recovery activities that must follow a large-scale mass casualty event. We have never seen the number of casualties in the United States we are preparing for today. We do have the threat of an enemy who will strike within the United States with the purpose of inflicting mass numbers of casualties on the civilian population. We must maintain the perspective that even the smallest chance of such an incredibly devastating event, whether manmade or natural, warrants our full attention. If there is no other motivating factor, the possibly such an event must suffice.

Vaccines

Kent J. Stock

HISTORICAL BACKGROUND

The Biological and Toxin Weapons Convention was established in 1972. Members of the convention produced a treaty that prohibited the development, production, stockpiling, and acquisition of biologic weapons. This was the first comprehensive, international effort to ban biologic and chemical weapons since the Geneva Protocol in 1925, and it was the first international treaty to ban an entire class of weapons. The treaty was opened for signature on April 10, 1972, and entered into force on March 26, 1975. The treaty has been signed by 144 nations, including the United States and the Soviet Union.

On Oct. 4, 2001, a case of inhalational anthrax was reported in Florida.¹ Epidemiologists at the Centers for Disease Control and Prevention (CDC) later identified and confirmed 22 cases—11 cases of inhalational anthrax and 11 cases of cutaneous anthrax.² The dissemination of these anthrax spores via letters through the U.S. mail appeared to be an intentional act of bioterrorism. In the aftermath of the Al-Qaida attacks on the World Trade Center and Pentagon buildings, this pernicious act illustrated our country's vulnerability to terrorist attacks, particularly those involving the use of biologic weapons. In response to the terrorist attacks the United States, the federal government passed the USA Patriot Act in October 2001 and the Public Health Security and Bioterrorism Preparedness and Response Act in June 2002. These acts created the Department of Homeland Security and empowered the Department of Health and Human Services (DHHS) to begin efforts to protect the civilian population against future attacks with biologic weapons by enhancing surveillance and promoting preparedness.

DHHS, in conjunction with the CDC and National Institutes of Health, convened members of the research community to discuss the development of a research agenda and strategic plan for biodefense research. These efforts to counter bioterrorism focused on a group of microbes that included *Yersinia pestis*, *Francisella tularemia*, *Bacillus anthracis*, variola major virus, *Clostridium botulinum*, and the hemorrhagic fever viruses.³ Variola major virus (smallpox) was particularly feared because of its high mortality rate, the absence of specific therapy, and the highly susceptible general population.⁴ The CDC published its *Interim*

Smallpox Response Plan and Guidelines in November 2001.⁵ These guidelines were later updated in 2002.⁶ This was the first time a U.S. government agency sponsored and implemented a large-scale civilian vaccination strategy in anticipation of a potential threat with a biologic weapon.

The initial debate focused on whether the entire population should be vaccinated to eliminate the threat of a future attack or whether to institute a targeted vaccination program only after an attack occurs or if the likelihood of an attack is deemed high by government officials. CDC officials decided to support a "ring vaccination" approach after a case of smallpox was identified.⁵ The vaccination approach focuses on a surveillance and containment strategy. It involves the identification of smallpox cases, isolating those individuals, and vaccinating contacts and household contacts of those contacts.⁵ The plan did not recommend mass vaccination in response to a documented case. Additional measures were instituted to voluntarily vaccinate first responders and healthcare and emergency personnel who would be responsible for caring for smallpox victims. Unfortunately the response on behalf of healthcare and emergency personnel was subdued due to concerns regarding vaccine safety and the low likelihood of a smallpox threat.

Large-scale vaccination programs in noncivilian populations have been conducted in the past. In 1998, the U.S. Department of Defense recommended vaccinating military recruits against anthrax. Opposition by some recruits was voiced because of a fear of unwanted side effects. Recent efforts to vaccinate military personnel in Iraq against anthrax have been conducted with substantial compliance and success.⁷ Implementation strategies for mass vaccination programs against anthrax in the military are continuing to be studied closely so that the lessons learned can be applied to civilian vaccination programs.

IMMUNITY

Immunization is the method of artificially inducing immunity to prevent the development of disease. The artificial induction of immunity was first demonstrated by Edward Jenner in 1796.⁸ He observed that milkmaids

who had contracted cowpox were immune to smallpox. He developed the practice of vaccination, inoculating fluid from cowpox lesions into the skin of susceptible individuals. Inoculated individuals typically developed mild illness; however, some did develop disseminated infection with secondary complications.

Immunization can be induced via active or passive methods. Active immunization typically involves the administration of a vaccine to induce the host to produce an immune response against a particular microorganism. Passive immunization refers to the practice of providing temporary protection by passively transferring exogenously produced antibody, such as immune globulin, to a susceptible host. Immunizing agents include vaccines, toxoids, antitoxins, and antibody-containing solutions. Immunizing agents are derived from either animal or human sources.

The initial response of the immune system to the introduction of an antigen occurs after the primary exposure. After a period, one witnesses the development of humoral- and cell-mediated immunity. Circulating antibodies do not typically develop for 7 to 10 days. If an antigen is presented for a second time, an exaggerated humoral- or cell-mediated response occurs, called an “amnestic response.” These amnestic responses usually result in antibody formation within 4 to 5 days.

There are multiple determinants of immunogenicity. Immunogenicity is determined by the physiological state (e.g., nutrition, immune status, age) and the genetic characteristics (e.g., major histocompatibility complex polymorphism) of the host, the manner in which the immunizing agent is presented (e.g., route, timing of doses, use of adjuvants), and the composition and degree of purity of the antigen.

VACCINES

The ideal vaccine should possess the following characteristics⁹:

- The agent should be easy to produce in well-standardized preparations that are readily quantifiable and stable in immunobiological potency.
- It should be easy to administer.
- It should not produce disease in the recipient or susceptible contacts.
- It should induce long-lasting (ideally permanent) immunity that is measurable by available and inexpensive techniques.
- It should be free of contaminating and potentially toxic substances.
- Adverse reactions should be minimal and minor in consequences.

Current vaccines do not typically meet all of these criteria. Most possess limited efficacy or have unwanted side effects.

Vaccines typically consist of live-attenuated or killed-inactivated microbiological agents. Many viral vaccines contain live-attenuated virus (e.g., measles, mumps, rubella, oral polio). The vaccines for some viruses and most bacteria are killed-inactivated, subunit preparations

or are conjugated to immunobiologically active proteins (e.g., tetanus toxoids). Live-attenuated vaccines tend to elicit a broader immunological response on behalf of the recipient. Live-attenuated vaccines also tend to elicit a more durable immunological response. Killed-inactivated vaccines, which typically have a lesser antigenic mass, require booster vaccinations.

Currently licensed vaccines are both effective and safe; however, adverse events are associated with vaccine administration. Adverse events can be both trivial and life-threatening. Examples include injection site reactions, fever, irritability, and hypersensitivity reactions. Administration of live viruses can sometimes lead to disseminated infection and therefore is contraindicated in certain populations (e.g., immunocompromised). The National Childhood Vaccine Injury Act was passed by Congress in 1986. This act required the reporting of certain vaccine adverse events to the secretary of the DHHS. It also led to the creation of the Vaccine Adverse Events Reporting System.¹⁰ The system's primary function is to investigate and study new vaccine adverse events or changes in the frequency of known vaccine adverse events. The reporting system has helped identify rare adverse events, including intussusceptions associated with rotavirus vaccine,^{11,12} myopericarditis and ischemic cardiac events among smallpox vaccine recipients,¹³ and viscerotropic and neurotropic disease after yellow fever virus administration.¹⁴

The development of vaccines and the implementation of vaccination strategies have had a profound impact on childhood morbidity and mortality.¹⁵ From 1951 to 1954, approximately 16,000 cases of polio occurred each year in the United States, four years before vaccine licensure.¹⁶ The impact on the health of schoolchildren was tremendous. In response to the health hazards posed by polio, the United States began a field trial in 1954, in which thousands of susceptible schoolchildren were administered an unlicensed, live polio vaccine developed by Dr. Jonas Salk. *Life* magazine referred to the study as “the biggest experiment in U.S. medical history.” Twenty-five years after this historic experiment, the last recorded case of wild-type poliovirus in the United States occurred.¹⁷ In 1988, the World Health Organization launched the global polio eradication effort. Polio is now eradicated from the Western hemisphere, and in 2003 there were only 677 cases recorded worldwide in six different countries.

BIOLOGIC AGENTS

The CDC has designated three categories of biologic agents according to their potential as weapons of terrorism.¹⁸ Category A agents were given the highest priority because they are easily disseminated or transmitted, associated with high mortality rates, can cause panic and social disruption, and require special action for public preparedness. Category B agents are moderately easy to disseminate, cause moderate morbidity and low mortality, and require enhanced diagnostic capacity and disease surveillance. Category C agents include emerging pathogens

that have the potential for becoming biologic weapons in the future. Immunizing agents are available against several bioterrorist agents.

Category A

Anthrax (*B. Anthracis*)

BioPort Corp. in Lansing, Mich., manufactures the only human vaccine for the prevention of anthrax in the United States. Licensed in 1970, the vaccine was formerly known as Anthrax Vaccine Adsorbed (AVA). Its current name is BioThrax. The vaccine is prepared from a cell-free culture filtrate of a nonencapsulated, attenuated strain of *B. anthracis*.¹⁹ The antigen primarily responsible for inducing protective immunity is the protective antigen.²⁰ The immunization schedule involves six immunizations. The vaccine is administered subcutaneously in a 0.5-mL dose at 0, 2, and 4 weeks and 6, 12, and 18 months.²¹ Annual boosters are recommended thereafter. The available vaccine is recommended for select laboratory workers and military personnel.²² The vaccine is effective for the prevention of cutaneous disease in adults. Studies in nonhuman primates suggest protection from inhalational disease as well.²³ Adverse events include injection site reactions, fever, chills, myalgia, and hypersensitivity reactions. The vaccine is not licensed for use in children or pregnant women. The vaccine is not currently licensed for postexposure prophylaxis; however, vaccination with antibiotic administration would be recommended in the event of a biologic attack.⁴

Botulism (*C. botulinum*)

Therapy for botulism includes passive immunization with antitoxin. Human-derived botulinum antitoxin (formerly known as Botulism Immune Globulin Intravenous [BIG-IV]) is only indicated for use in cases of infant botulism.²⁴ Efficacy was demonstrated in a randomized trial.²⁵ In the United States, the California Department of Health can be contacted for procurement of BIG-IV. Trivalent equine botulinum antitoxin (types A, B, and E) and bivalent antitoxin (types A and B) are available for the treatment of foodborne or wound botulism. Equine antitoxin can be obtained from the CDC through state health departments. Intravenous administration of equine antitoxin neutralizes toxin molecules that have not yet bound to nerve endings. One vial (10 mL) of trivalent antitoxin (7500 IU of type A, 5500 IU of type B, and 8500 IU of type E) is administered per patient.²⁶ No additional doses are recommended. The half-life is estimated to be 5 to 8 days.²⁷ A hypersensitivity reaction has been reported in 9% of individuals.^{27,28} A retrospective study demonstrated that the early administration of antitoxin (within 24 hours of onset of symptoms) was associated with an overall mortality rate of 10%, compared with 15% in patients in whom antitoxin was administered after 24 hours of symptoms and 46% in patients who did not receive antitoxin at all.²⁹ Equine antitoxin is not currently recommended for use in cases of infant botulism. This is

largely due to the concern for hypersensitivity reactions. There are no licensed botulism toxoid vaccines currently available.

Smallpox (Variola Major)

Vaccination against smallpox was first performed by Edward Jenner in 1796.⁸ The currently available smallpox vaccine was first licensed in 1903.³⁰ The last case of smallpox in the United States occurred in 1949. Routine vaccination against smallpox was discontinued in the United States in 1972. Eradication of smallpox was officially declared in 1980 by the World Health Organization. Wyeth Laboratories, Inc., the only licensed producer of smallpox vaccine in the United States, discontinued distribution to the civilian population in May 1983.³¹ By 1984, only the CDC in Atlanta, Ga., and the Research Institute of Viral Preparations in Moscow, Russia, possessed variola virus isolates. Because of the threat of bioterrorism, the United States produced 15 million doses of smallpox vaccine derived from the New York Board of Health vaccinia strain.³² An additional 280 million doses of vaccine were to be available by late 2002. Sanofi-aventis has also identified 70 to 90 million doses of vaccinia vaccine from storage that will be added to the nation's stockpile.³²

The only licensed smallpox vaccine in the United States is a lyophilized, live preparation of vaccinia virus.²⁴ The vaccine preparation contains vaccinia virus, distinct from the variola virus, which causes smallpox and cowpox virus that was initially used by Jenner. The vaccine is highly effective in preventing smallpox. Protection typically wanes 5 to 10 years after a single dose.²⁴ The federal government has recently contracted for the production and purchase of a new vaccine preparation. It is derived from tissue cell culture and may become available for use in the next 1 to 2 years. Modified vaccinia virus Ankara (MVA) may be suitable as a new smallpox vaccine.³³ It is an attenuated strain and may be safer than unattenuated products. Smallpox vaccine is currently approved by the U.S. Food and Drug Administration for use in persons in special risk categories, including laboratory workers. The CDC recommended and implemented a voluntary vaccination plan for public safety and public health personnel because of the threat of bioterrorism.

The vaccine is administered with the use of a bifurcated needle. A droplet of vaccine is held by capillarity action between the two tines. The needle is introduced into the epidermis. Fifteen perpendicular strokes are rapidly made in a 5-mm area. The site should be covered with a loose, nonocclusive dressing. One should avoid touching the area to avoid transferring the virus to other body sites. An evolution of skin lesions will occur at the site of inoculation 3 to 21 days after inoculation.²⁴ The lesion will eventually scab and leave a scar.

Smallpox vaccine is considered safe, but adverse events are described. Approximately 70% of children experience fever.²⁴ Injection site pain and myalgia are other minor side effects. Complications include postvaccinial encephalitis (12.3/1 million primary vaccinations), progressive vaccinia (1.5/1 million primary vaccinations), eczema vaccinatum (38.5/1 million primary vaccinations), generalized vaccinia (241.5/1

million primary vaccinations), inadvertent inoculation (529.2/1 million primary vaccinations), rashes (1/3700 vaccinated; erythema multiforme is the most common), Stevens-Johnson syndrome (rare), and myopericarditis (<1/12,000 vaccinated persons).^{13,34,35} Death occurs as a result of life-threatening reaction to the vaccine in about 1 per 1 million primary vaccinations.³⁴ Smallpox vaccine should not be administered to individuals with atopic dermatitis or eczema; acute, active, or exfoliative skin conditions; altered immune states; pregnant or breast-feeding women; children younger than 1 year; or individuals with allergy to any vaccine component.³⁶

The smallpox vaccine can be used for postexposure prophylaxis. If administered within 96 hours of exposure, it can prevent or significantly decrease the severity of disease experienced by victims.^{37,38}

Plague (*Y. pestis*)

The commercially available plague vaccine was first licensed in 1911.³⁰ It was a formaldehyde-killed, whole bacilli vaccine. It was administered at 0 and 4 weeks and 6 months as a primary series. Boosters were administered in 6-month intervals for 3 doses, then every 1 to 2 years thereafter. The vaccine did not prevent the development of pneumonic plague, but it did have some protective effect against bubonic disease.^{39,40} Adverse effects included local reactions and headache. Hypersensitivity and severe systemic reactions were rare.⁴¹ The vaccine was administered to high-risk individuals, including military personnel working in endemic areas, laboratory workers working directly with *Y. pestis*, or researchers working with animals in plague enzootic areas. The manufacturer discontinued production of the vaccine in 1999, and it is no longer commercially available. Research is being conducted to produce a vaccine that is protective against pneumonic plague.⁴²

Tularemia (*F. tularensis*)

The first tularemia vaccine was developed in the Soviet Union in the 1930s. It was a live-attenuated vaccine and was administered to millions of individuals who resided in tularemia-endemic regions.⁴³ An investigational live-attenuated vaccine derived from the avirulent live vaccine has been administered in the United States. The vaccine was reserved for laboratory workers who work routinely with *F. tularensis*.⁴⁴ This product is currently under review by the Food and Drug Administration and is not currently commercially available. In one retrospective study, the live vaccine offered some protection against acute inhalational tularemia among laboratory workers.⁴⁵ The live vaccine did not protect against ulceroglandular disease, but individuals who received the vaccine had milder symptoms. Vaccination is not currently recommended for postexposure prophylaxis due to its limited efficacy.

Hemorrhagic Fever Viruses

This category refers to four distinct families of viruses. Filoviridae includes the Ebola and Marburg viruses.

Arenaviridae includes the Lassa virus and New World Arenaviridae. Bunyaviridae includes Nairovirus, Phlebovirus, and Hantavirus. Flaviviridae includes dengue, yellow fever, Omsk hemorrhagic fever, and Kyasanur Forest disease. All of these viruses are associated with clinical disease that produces fevers and a bleeding diathesis in humans. There are no licensed vaccines for any of the hemorrhagic fever viruses, except for yellow fever.

The yellow fever vaccine was initially licensed in 1953.³⁰ It is a live-attenuated vaccine that is highly effective in travelers to endemic areas.⁴⁶ It is not recommended for postexposure prophylaxis because of the virus' short incubation period.

Research is being conducted on the development of vaccines for several hemorrhagic fever viruses, including Ebola virus.⁴⁷ Research efforts are limited by the need for BSL-4 laboratory space. BSL-4 laboratory space is designed for maximum containment. This lab is used to provide scientists with a safe environment to study deadly pathogens for which there are no available treatments or vaccines.

Category B

Q Fever (*Coxiella burnetii*)

No human vaccine is currently available in the United States.

Brucellosis (*Brucella* Species)

No human vaccine is currently available in the United States.

Glanders (*Burkholderia mallei*)

No human vaccine is currently available in the United States.

Melioidosis (*Burkholderia pseudomallei*)

No human vaccine is currently available in the United States.

Encephalitis (Alphaviruses)

Examples include eastern equine and western equine encephalomyelitis and Venezuelan equine viruses. No human vaccine is currently available in the United States.

Typhus Fever (*Rickettsia prowazekii*)

No human vaccine is currently available in the United States.

Toxins (e.g., ricin, staphylococcal enterotoxin B)

No human vaccine is currently available in the United States.

Psittacosis (*Chlamydia psittaci*)

No human vaccine is currently available in the United States.

Food Safety Threats (e.g., *Salmonella* Species, *Escherichia coli* 0157:H7)

Two typhoid vaccines are currently licensed for use in the United States. The first oral vaccine was licensed for use in 1990.³⁰ The oral Ty21a vaccine is indicated for children age 6 and older and for adults.²⁴ Individuals ingest one enteric-coated capsule every 2 days for a total of 4 doses. Each capsule should be taken with cool liquid, 1 hour before a meal and must be kept refrigerated. The manufacturer recommends a new complete series every 5 years.²⁴ The oral vaccine is associated with minimal unwanted side effects. Reported side effects include abdominal discomfort, nausea, vomiting, fever, headache, and rash.²⁴ The first parenteral vaccine was licensed for use in 1917.²⁴ The Vi capsular polysaccharide vaccine is indicated for individuals age 2 and older.²⁴ The vaccine is administered intramuscularly, one 25-ug (0.5-mL) dose. Booster doses are recommended by the manufacturer every 2 years.²⁴ Adverse effects associated with the parenteral vaccine include fever (0%-1%), headache (1.5%-3%), and injection site reactions (7%).²⁴ The demonstrated efficacy of both vaccines ranges from 50% to 80% after a primary series.³⁰ Immunization is currently recommended for travelers to endemic areas, people with an exposure to a documented *Salmonella typhi* carrier, and laboratory workers with frequent contact with *S. typhi*.³⁰ General contraindications include children younger than 2, pregnant women, and people with a history of a hypersensitivity reaction to the vaccine. The oral Ty21a vaccine should not be administered to individuals actively taking antibiotics, especially sulfonamides or mefloquine.³⁰ One should allow the individual to stop taking these medications for at least 24 hours before administering the vaccine. The oral vaccine should not be administered to immunocompromised individuals.³⁰

No human vaccine is currently available in the United States for the prevention of illness caused by *E. coli* 0157:H7.

Water Safety Threats (e.g., *Vibrio cholerae*, *Cryptosporidium parvum*)

No human vaccine is currently available in the United States for the prevention of illness caused by *V. cholerae* or *C. parvum*. Two oral cholera vaccines are available elsewhere (WC/rBS and CDV 103 Hgr).²⁴ Neither vaccine can be administered to children younger than 2.²⁴ They are not effective against *V. cholerae* 0139 Bengal.²⁴ The World Health Organization no longer recommends immunization for individuals traveling to or from cholera-infected regions. Cholera vaccine is not required for entry into any country at this time.

Category C

Emerging Threat Agents (e.g., Nipah virus, Hantavirus)

No human vaccine is currently available in the United States for Nipah virus or Hantavirus.

Miscellaneous Agents

Influenza

The currently available inactivated influenza virus vaccine was first licensed in 1945.³⁰ The vaccine is produced in embryonated hen eggs. It is composed of inactivated whole virus, split product, or neuraminidase/hemagglutinin subunit vaccines.²⁴ These vaccines are multivalent and typically contain three virus strains.²⁴ The vaccines are developed annually to match the predicted strains of influenza that are expected to predominate in the coming season. The opportune time to vaccinate people in the United States is October through November. Peak influenza season typically occurs December through March. The vaccine typically offers protection for 4 to 6 months.⁴⁸ Vaccine efficacy is estimated at 30% to 80%.⁴⁸ The efficacy is influenced by the population, end points measured, and match between vaccine and circulating virus. Febrile reactions are rare in children younger than age 13.²⁴ Fever tends to occur within 6 to 24 hours of administration of vaccine in children younger than 24 months.²⁴ Local reactions occur in 10% of individuals 13 years or older.²⁴ A slight increase in Guillain-Barré syndrome was seen in vaccine recipients.²⁴ This resulted in an excess rate of approximately 1 per 1 million people immunized.²⁴ People with a history of Guillain-Barré syndrome or anaphylaxis to egg protein, chickens, or other vaccine components should not receive the inactivated vaccine.²⁴ The 2004 Advisory Committee on Immunization Practices recommends the following primary groups for vaccination⁴⁹:

- All children 6 to 23 months old
- Persons older than 65
- Pregnant women
- Persons with chronic medical conditions who are at increased risk for influenza-related complications
- Healthcare workers
- Residents of nursing homes and other chronic care facilities
- Household contacts of persons who live, care for, or have frequent contact with persons at high risk and who can transmit influenza to those persons at high risk

Intranasal vaccines also have been developed. Inactivated intranasal vaccines have been shown to be more immunogenic than the injected vaccine.⁵⁰ Nasally administered live-virus vaccines also have been developed. These vaccines are made with cold-attenuated influenza viruses. The advantage of these vaccines is that they are relatively easy to administer and induce mucosal immunity.⁴⁸ Vaccine recipients reported rhinorrhea (44%) and pharyngitis (26.6%).⁵¹ Efficacy reached 93% in a study involving healthy children.⁵² These unwanted side effects typically occurred within 7 days of administration of the vaccine. Intranasally administered live-virus vaccine should be encouraged for healthy persons ages 5 to 49 years.⁴⁹ Pregnant women, healthcare workers caring for severely immunocompromised patients in special care units, and persons caring for children younger than 6 months should not receive the live virus vaccine.⁴⁹

FUTURE EFFORTS

Vaccine research continues to advance. Investigators from both private and public institutions are vigorously pursuing more effective and safer vaccine products. Research interests include developing new vaccine delivery systems (e.g., DNA vaccines, novel routes of administration, the creation of combination products, and eliminating unwanted side effects).

Because of the perceived increase in the threat of bioterrorism, several government agencies have been charged with directing their resources and efforts to develop vaccines that will protect the general population from certain biologic agents. The National Institutes of Health and its subordinate, the National Institute of Allergy and Infectious Diseases, are developing medical countermeasures in the form of therapies, vaccines, and diagnostic tools to protect the country from deliberate attacks with biologic agents.⁵³ Specific research agendas for agents of bioterrorism are outlined in detail by several government agencies.^{54,55} Approximately \$652 million of the 2005 National Institutes of Health biodefense research budget will be dedicated to vaccine research.⁵⁶

QUARANTINE AND ISOLATION

*Webster's New World Dictionary*⁵⁷ defines *quarantine* as "the period, originally forty days, during which an arriving vessel suspected of carrying contagious disease is detained in port in strict isolation." The word was derived from the Italian *quarantena*, which meant "space of forty days."⁵⁷ *Quarantena* was imposed on Italian merchants arriving home to port during the 1300s at the height of the Black Plague outbreaks in Europe. Modern users have applied the term to several scenarios during the era of bioterrorism to refer to travel limitations, restrictions on public gatherings, and isolation of sick individuals to protect others. This has led to much confusion and miscommunication. Recent efforts by several authors have meant to clarify this situation by providing a contemporary definition. They interpret quarantine as referring to the "compulsory physical separation, including restriction of movement, of populations or groups of healthy people who have been potentially exposed to a contagious disease, or to efforts to segregate these persons within specific geographic areas."⁵⁸ Human quarantine is justified under the terms of the public health contract.⁵⁸ Adverse consequences that have occurred historically with quarantine actions have included the increased risk of transmission among the quarantined population, precipitation of violent acts, and the potential for ethnic bias influencing decision making.^{55,60,61}

Isolation refers to "the separation and confinement of individuals known or suspected to be infected with a contagious disease to prevent them from transmitting disease to others."⁵⁸ The terms should not be used interchangeably.

Occupational Medicine: An Asset in Time of Crisis

Tee L. Guidotti

Corporations and other large institutions have become deeply concerned with continuity of operations and the security of their personnel. The new urgency placed on these functions since Sept. 11, 2001, has drawn attention to a substantial resource already in place in such organizations—their occupational health services. The imperatives of corporate security and homeland defense have, in turn, invigorated and expanded the mission of occupational medicine, one of the oldest recognized medical specialties.¹

Occupational health services are most familiar in the manufacturing sector and in the setting of a plant's medical clinic. Typically, such services include at least one occupational health nurse (also a professional specialization); an occupational physician (typically on contract); and support staff, all of whom report on a regular basis to a plant manager and are responsible professionally to a corporate medical director, who himself or herself serves as a traveling troubleshooter, in-house resource on health issues, and auditor for health affairs. This physician-led, health-centered team typically is engaged in regular interaction and troubleshooting in collaboration with an industrial hygienist and safety officer, who are usually oriented more toward process and plant operations, documenting regulatory compliance, and identifying and measuring health hazards. These hazard-oriented professionals usually report to a different manager or directly to the plant manager. This basic pattern was once the norm in industry, but the dramatic reorganization in industry, management focus on core business, and the rise of the service sector have forged a new pattern, in which services are outsourced to contractors and consultants.²

However, whichever pattern is followed in a particular enterprise, the following essentials are in place in most large operations: a means of monitoring the health of workers, a system for documenting their health, a system for documenting and evaluating hazards, a mechanism for responding to emergencies, and a panel of health consultants.³

This is exactly the type of infrastructure that large organizations need so that they can respond to disasters and protect the security and continuity of operations.⁴

Thus, large organizations already have in place a structure on which to build to protect their operations and personnel. Involvement of the occupational health service in emergency management, which was common in the past, is a natural extension into disaster medicine, involving training and preparation for consequence management and mitigation activities,⁵ preparedness for a response indigenous to the physical plant, and planning for the management of risks inherent to the operation.^{2,6} The occupational health service also has an important place at the table as an active member of the healthcare team, interacting with local prehospital care providers and hospitals on the Local Emergency Preparedness Committee (LEPC).

Box 23-1 presents the usual functions of a corporate medical department, provided or supervised by occupational physicians.² These functions have traditionally been clustered in a few broad missions: to protect health, to support productivity, to reduce loss and liability, to manage health affairs, and to ensure compliance with regulations and best practice for the industry. These functions have traditionally been viewed as support functions, not part of the business operations of the organization. Indeed, this is why these functions were subject to outsourcing throughout the private and government sectors during the 1980s and 1990s.

A new realization of the criticality of these functions is spreading in the corporate sector, stirred by the awareness of the profound threat of major industrial incidents and potential terrorist attacks to the continuity of operations and the survival of key personnel.^{4,7} The role of the occupational physician is increasingly recognized for its potential to contribute to the survival of the enterprise, not just its efficient operation.³ For example, Dow received an award from the state of Michigan Public Health Department for assistance to the state, particularly with respect to its efforts in disaster planning.

The usefulness of a trained, well-informed, prequalified medical resource for dealing with incidents on-site is obvious. These incidents may include, but are certainly not limited to, sending infectious material through the mail to company personnel and using company equipment, such as airplanes or, potentially, chemical plants or

BOX 23-1 CORE FUNCTIONS OF AN OCCUPATIONAL HEALTH SERVICE

1. Acute care for injured employees
 - Providing care on-site
 - Monitoring care given off-site
2. Preplacement evaluations that assess fitness to work
 - Assessing functional capacity to do the job
 - Assessing need for accommodation under the Americans with Disabilities Act
3. Functional evaluation of employees after hire
 - Fitness-to-work evaluations that assess the recovery and functional capacity of injured employees to return to work and what accommodations may be needed
 - Impairment evaluation for injured workers who are the subject of workers' compensation claims
 - Certification of time off work for workers with a nonoccupational illness or injury (this is often performed by other physicians)
4. Review of workers' compensation claims for causation
5. Periodic health surveillance of employees exposed to a particular hazard, such as noise, chemicals, dusts, or radiation (this often takes the form of a medical examination, often conducted annually)
6. Investigation of exceptional hazards, disease outbreaks, unusual injuries, fatalities, or other emerging issues
7. Prevention, health promotion, and educational programs designed to enhance the health of employees and to increase productivity
8. Management of the health problems of employees on-site to reduce absence and disability
9. Advice and consultation to management on issues of health, health and workers' compensation insurance, and regulatory issues in occupational health
10. Disaster planning and emergency management on-site
11. External communications on health issues (e.g., with local public health agencies and local physicians)
12. Managing relations between the organization and local hospitals and the medical community
13. Employee assistance programs for employees with problems involving alcohol and drug abuse or other addictive behaviors, such as gambling, that interfere with work
14. Executive wellness programs, such as special medical evaluations or monitoring health problems among senior executives

Larger and more complex organizations may also involve the occupational physician in managing environmental risks, product safety, contracting for health services, representing the organization in industry-wide health activities, and proactive programs for preparedness, risk management, and other senior management functions.

storage facilities, as instruments of assault. The occupational physician, who is trained in hazard assessment, also may assume the responsibility of determining when a site is safe to re-enter or when a facility can be reopened. He or she also would be responsible for managing the psychological consequences of an assault.

Less obvious, but equally valuable, is the role that such physicians may play in managing the consequences of widespread disruption to business operations due to major threats and in protecting the business, the product, and the brand against catastrophe in cases in which a company's products, facilities, or operations are used to deliver a threat or become targets for terrorist activity. In time of crisis, the occupational physician may help get the community back on its feet by helping to keep an employer open or critical infrastructure functioning.⁸

Similarly, the occupational physician has been called on to manage the corporate response to serious health-

related issues, such as traveling to areas in which severe acute respiratory syndrome (SARS) and other emerging infections are a risk; rapidly investigating suspicious outbreaks of disease or exposure to potential hazards; and determining when re-entry and reoccupancy is possible in contaminated facilities, such as post office facilities contaminated with anthrax.⁴ Several companies, including Cathay Pacific, participated in an informal monitoring network during the SARS epidemic to share observed trends and experience when the information they needed was not forthcoming from conventional sources. Procter and Gamble, alerted to the emerging problem by its own corporate medical leader for China, instituted SARS precautions a month before any official warnings were advised.

These functions build on the traditional involvement of physicians in disaster planning, as well as health protection for employees.^{2,6} Disaster planning has traditionally been one of the core functions of the medical department and occupational physicians in corporate settings. The physician has usually assumed responsibility within the organization for planning the medical response to emergencies, identifying facilities and resources for dealing with serious injuries and mass casualties, and providing health protection for key personnel, if required. Although outsourcing has reduced the direct involvement of occupational physicians in planning emergency management in many organizations, particularly in the service sector, this function has not been completely replaced by external consultants because it requires a practitioner with intimate knowledge of the operations, hazards, workforce, and policies of the organization.

The occupational physician can add value to the management of catastrophic consequences in many other ways. These include the following:

- Survival of key personnel in a catastrophic event
- Continuity of business after a catastrophic event
- Instant connectivity to resources for assistance in a health-related emergency
- Surveillance of the workforce and the early detection of an outbreak
- Integration of emergency response with public health agencies
- Surge capacity in the event of a local event that requires mobilization of all available medical resources
- Vaccination programs and other protective measures
- Establishing on-site consequence management and mitigation programs
- Developing decontamination plans
- Providing specialized, sector-specific expertise to emergency managers
- Advising on effective personal protective equipment (PPE)
- Liaising with the LEPC, prehospital care, and hospitals
- Continuing education and training on-site and in the community of the indigenous risks inherent to the operation
- Accessing material safety data sheet information
- Leading any after-action discussion to bring about process and system improvement

Performing these duties effectively requires committed time for preparedness activities and an occupational health service that is structured and whose providers are trained to play such a role in time of crisis. However, it is costly and inefficient for even large corporations to dedicate a full staff and support structure for the management of an event that may or may not materialize. This is why adaptation of the existing occupational health service makes sense for many employers, especially those in critical or hazardous industries.

Incorporating emergency management into the mission of the occupational health service builds allows for an emergency response system that a business would not otherwise have. The same resources used for tracking employees' health can be used for surveillance to detect potential disease outbreaks due to bioterrorism. The technology of hazard identification and measurement can be applied to detect chemical or radiation threats. The medical staff on duty primarily to monitor health and to provide timely clinical care can provide surge capacity in time of crisis. Health protection for senior executives, and the personal knowledge that this entails, can keep key personnel on the job and safe, especially when they are moved to new locations or are operating under conditions of stress and potential risk. The skills that are normally applied to ensuring a safe workplace can be used to determine when it is acceptable to return to work or to venture into a facility that has been contaminated or damaged. Planning for foreseeable industrial disasters can inform and refine the response to unforeseen threats, given that sophisticated disaster planning is a matter of identifying resources and contingencies, not deriving detailed plans for single-threat incidents.

Perhaps most attractive to cost-conscious managers is that investment in expanding the emergency management capacity within an occupational health service is not "lost" if an event never occurs. The same capacity supports and enhances the traditional occupational health services that industry and government employees require and may lead to cost savings, increased productivity, and reduced liability in their own right.

Occupational physicians, who are conscious of their responsibility and aware of their own position on the firing line along with the employees and executives they protect, have been preparing themselves for an expanded role in emergency management. The principal specialty organization, the American College of Occupational and Environmental Medicine (ACOEM), has for some time offered training in the characteristics of weapons of mass destruction (well before Sept. 11, 2001, and the anthrax assaults), emerging infections (particularly using the model of SARS), and "tabletop" exercises to train participants in emergency management and consequence management for disasters and mass casualties. Immediately after the Sept. 11, 2001, tragedy, an ACOEM task force produced a guide to the management of mental health issues among survivors of mass assaults, disseminated it to all members, and posted it on the ACOEM Web site—all within four days. This achievement was unique and widely admired among medical specialty organizations.

In 2003, leaders within ACEOEM developed the Occupational Health Coordinating Group (OH-CG) as a resource for coordinating responses, accessing management resources, and sharing information in times of crisis. It includes physicians, occupational health nurses, industrial hygienists, and other occupational health professionals. The OH-CG is a working council, sponsored by the Department of Health and Human Services, within what will eventually become a health-sector ISAC (Informational Sharing and Coordination) organization. This is a highly unusual and encouraging development in many respects. ISACs have official status with the Department of Homeland Security and are intended to coordinate the planning response of critical sectors of the American economy and society. They have been formed, for example, in industry sectors such as critical utilities and transportation. The OH-CG was the first health-sector ISAC to be created and is now the Occupational Health Subcommittee of the Healthcare Sector Coordinating Council, the ISAC for healthcare. This is a remarkable achievement for a relatively small medical specialty. Because occupational health is cross-cutting across industries, the OH-CG is expected to serve as a resource for other critical sectors rather than to focus primarily on the health sector per se and in so doing uniquely relate to other ISACs as much as the one of which it is a part. Its mission is to provide occupational health professionals with what they need and when they need it in a time of crisis through channels that do not depend on any one mode of communication.

How might an organization prepare its occupational health department to respond on this scale in a crisis? Partly, the answer is to build an effective and efficient team. Teamwork comes from training and planning but also from regular personal contact and cooperation. A team that functions well in the complex duties of an occupational health service and that already knows the operations, workforce, and facilities is more likely to function well in an emergency than would an outside provider, who may not be around during a crisis.

Another part of the answer is to build redundant information and communication systems that can quickly retrieve critical information on hazards, disease or injury patterns, and individual health records in an adverse environment. Occupational health systems may require upgrading to do this effectively, but the technology is readily available. Partnerships within the LEPC, local industry, and other like facilities not only reduce the initial and ongoing costs but also enable more efficient planning, training, and response.

Acquiring the necessary expertise is obvious. The occupational health staff may require special training to take on the additional functions, but this is not much of a stretch from current duties. County emergency managers are eager to share training opportunities through grants and other programs within the public domain. On-site training and response in coordination with local prehospital care using strategies of consequence management and mitigation, education, decontamination, and PPE will support Occupational Safety and Health Administration efforts to protect workers and may reduce liability exposure for the organization's insurers. The expense for pre-

paredness may be justified by potential reductions in insurance premiums, as well as reduction of loss in the event of an emergency.

Establishing networks and agreements for mutual assistance may be critical. Here, the occupational health staff can coordinate arrangements with local hospitals, specialist practitioners, public health agencies, and first responders in advance and maintain personal relationships required for smooth operation in the event of a crisis. The first step is to forge an active participant's role in the LEPC. Some counties have a more active, dynamic, and responsive LEPC than others do. An occupational health service for a large organization has the opportunity to lead and become the backbone of emergency management in the community.

Facilities planning may be required, taking into account the characteristics of the site for evacuation, securing the premises but preserving access for ambulances and first responders, and defining areas of the plant for operational response (e.g., for staging rescue operations, triage, stabilizing casualties, decontamination, and "incident command"⁹ activities). Even locations without special hazards may benefit from such contingency planning in the event of an external threat. For example, the first anthrax assault was in the office of a newspaper, not normally a high-risk location.

Under various contingencies, surge capacity may be projected, as well as whether to call in help for managing mass casualties on-site (especially if local hospitals are not functioning or cannot be reached), to assist other units in a mutual assistance pact, or to perform services such as mass immunizations. On-site decontamination may have to be continued at the hospital or a second location away from the industrial incident. Surge capacity operations may be created away from the hospital under the direction of the LEPC, county emergency manager, or hospital. This may include separate healthcare mutual aid agreements specific for the incident and secondary triage and treatment provided by trained physicians and other healthcare providers through the use of vendor agreements or prepositioned equipment and supplies. This strategy will enable the hospital and community healthcare delivery system to operate at near-standard operations during an industrial incident. Any facility that has potable water, electricity, and shelter may participate. Pre-existing arrangements for accessing these sites should be spelled out under mutual aid agreements, vendor contracts, memoranda of understanding, or special circumstances agreements negotiated in advance between the county emergency management office, the hospital, or the local employer. Documentation of expenditures is a critical function, just as it is in the incident command structure,⁹ to reimburse all nonvolunteers and contracts executed in the response.

Certain routine functions can be anticipated and planned. For example, if anthrax or some other threat is determined to be a possibility for a business, procedures can be put in place in advance to protect employees, limit disruption, and rapidly evaluate evolving situations. This was done in a timely manner by DST Output, the nation's largest direct mail operation, on the advice of its medical director. Planning is particularly important

to deter inevitable hoaxes and to prevent disruptions to business from ill-defined or unknown hazards. For example, the common scenario of an unknown "white powder" appearing on a loading dock or in an office can shut down operations for a day or more until a toxic substance is ruled out. Having the capacity on hand to show that it is harmless saves time and anxiety.

Confronted with a true emergency, most people behave in an adaptive, rational manner that helps them to get through the crisis and to mitigate personal damage or injury. Some are capable of helping others in an emergency.¹⁰ This response appears to be shaped, at least in part, by whether the emergency arises from a natural disaster or a "technological" event (an incident arising from human agency).⁶ The perception of an intentional assault may also shape the psychological response for some people. Some people in situations of perceived catastrophic risk behave irrationally, however, and demonstrate psychogenic symptoms and maladaptive behavior.¹¹⁻²² Dealing with anxiety-promoting perceptions and psychogenic symptoms among employees that arise from rumors or incidental illness occurring at the worksite requires skill in rapid assessment and in risk communication but can save an enterprise from devastating loss of confidence and potential loss from employees who may refuse to come to work. Distinguishing between human drama and a true emergency arising from a nonobvious cause is also a challenge that requires specialized expertise that is within the scope of the occupational physician.

An enterprise may be in a position to control its liability and potential loss from claims after a disaster by developing a flexible, effective emergency management capability within its occupational health services before a disaster event. In addition to reducing actual loss through planning and effective consequence management, which is most important, such an enterprise would also be able to show after the fact that it had done its due diligence in anticipating and preparing for plausible threats. This could reduce its exposure to punitive awards or claims based on negligence or omission. Legal opinions on this may vary, but it seems reasonable that a company that appears to be prepared is less likely to be accused after the fact of ignoring a foreseeable threat.

In the classic business model followed during times of business as usual, the priorities of corporate management in descending order are shareholder value and profitability, continuity of production and operations, and loss control and risk management. For government agencies, there is a similar set of priorities, with the mission of the agency coming first. However, in times of crisis, survival of the enterprise and protection of people take precedence. In the past, occupational medicine and occupational health services have always been perceived as support functions, facilitating management priorities, but not core business priorities. In the new era of threats to survival and business continuity, occupational health services and the physicians in them may play a role in the survival of the enterprise and its people. A wise organization, faced with an extraordinary threat, may look within to build its salvation on a functioning system that already serves its interests.

Worker Health and Safety in Disaster Response

Clifford S. Mitchell, Brian J. Maguire, and Tee L. Guidotti

This chapter addresses worker safety in disaster response, including evaluation and management of workers involved in a disaster, medical surveillance, legal and regulatory requirements related to worker exposures, and specific issues for particular worker populations. Protection of worker safety and health during and after a disaster requires careful planning, training, and integration of occupational medicine, nursing, industrial hygiene, safety, and environmental functions. Recent disasters, including the terrorist attacks of Sept. 11, 2001, and the use of anthrax in the postal system, have demonstrated the importance of integrating emergency preparedness with other aspects of occupational and safety and health.¹

PRE-EVENT PLANNING

The previous chapter discussed pre-event planning for a disaster, including the need for mutual assistance networks, facility planning and surge capacity, and consideration of potential threat agents. In addition, it is important to consider workforce preparation and training, not only for first and secondary responders, but for others who might potentially be involved in disaster response, including skilled support personnel and other categories of workers.² All workers should receive pre-event training and “real-life” drills in certain basic aspects of disaster response, including:

- Egress and evacuation
- Use of personal protective equipment (PPE)
- Recognition of threats/hazards
- Activation of the emergency response system
- Incident command
- Their own specific functional role in an emergency

In addition, certain workers may need additional training, depending on their jobs. Some of these requirements are described in the U.S. Occupational Safety and Health Administration (OSHA) standard for hazardous waste operations and emergency response (HAZWOPER).³ The HAZWOPER standard describes worker safety requirements for hazardous waste or emergency

response sites that could involve chemical, biological, nuclear, radiological, or other hazards. OSHA distinguishes between training requirements for workers who need basic awareness training, those at the “operations level,” workers known as hazardous materials technicians (workers involved in stopping the release of hazards), workers with specific knowledge of the hazards involved, and the on-scene incident commanders.

Another aspect of pre-event planning involves PPE. Selection of PPE involves collaboration between industrial hygiene, safety, occupational medicine and nursing, and those involved in evaluating the potential risks and agents involved. The National Institute for Occupational Safety and Health (NIOSH) recently issued standards for respiratory protection against chemical, biological, radiological, and nuclear (CBRN) hazards.⁴

MANAGEMENT OF WORKERS INVOLVED IN DISASTER RESPONSE

During the disaster response, workers should receive limited briefings and training, sufficient to ensure that they are aware of the specific hazards they face on the site, that they are able to use their PPE appropriately, and that they understand the specific command structure and communications systems in place at the site. This applies to workers at the site of a large-scale disaster after the initial response. Hospital workers at receiving hospitals (“first receivers”) should also receive training, with the level of training depending on how likely the personnel are to have direct contact with contaminated patients.⁵ Training for first receivers should ideally take place well before an incident occurs because such training may not be practical during the emergency phase.^{6,7}

The medical management of acutely exposed individuals is discussed elsewhere in this text. There are, however, specific considerations for the management of workers who may be involved in disaster response, particularly if they have been potentially exposed to hazardous agents. These include use of biological monitoring for acute exposures, surveillance for illness and injury after exposures,

mental health considerations, and reporting requirements for specific exposures.

In many cases, workers who are designated first or secondary responders will already be enrolled in medical surveillance programs and will have received baseline or pre-event medical evaluations as required under the HAZWOPER standard.⁸ Although the standard does not specify the tests that must be performed, it does require "... [a] medical and work history (or updated history if one is in the employee's file) with special emphasis on symptoms related to the handling of hazardous substances and health hazards, and to fitness for duty including the ability to wear any required PPE under conditions (i.e., temperature extremes) that may be expected at the work site...."⁹ Typically, such workers also receive a clinical examination that includes laboratory tests (particularly baseline liver and renal function tests and hematological parameters), pulmonary function tests, chest roentgenograms, electrocardiograms, and other tests as indicated clinically. The selection of particular tests is based on the likelihood of exposure to and toxicological properties of possible agents and medical judgment about the utility of the tests as screening tests for disease or injury.

Workers involved in disasters where exposures to hazardous substances may occur should be evaluated as soon as possible after the incident. This evaluation has the following purposes:

- Obtain as complete a picture as possible of the exposure
- Estimate the potential for an internal dose
- Determine which, if any, biological measures of exposure may be appropriate
- Treat for acute exposures as needed
- Determine the need for follow-up, including surveillance

Estimating exposure and internal dose initially requires information about the hazards at the site, the activities and duration of exposure, type of PPE worn, and other relevant factors. For the medical provider, it is often helpful to create a questionnaire, in consultation with a knowledgeable industrial hygienist, that can be given to all of the potentially affected workers. Questionnaires help to standardize information and make it easier to see large numbers of patients efficiently. Questionnaires can include not only information about the current exposure, but also about past occupational and environmental exposures and pertinent medical history. There are several good references available for a standardized occupational/environmental history form.¹⁰

Medical surveillance requirements will depend on the agent(s) involved and the exposed population. Some substances, such as lead or asbestos, may have specific regulatory requirements for postexposure surveillance related to occupational exposure, but in many cases, it will be up to the healthcare provider to determine surveillance recommendations on a case-by-case basis.

Healthcare personnel should coordinate closely with industrial hygiene, safety, and environmental personnel to understand as completely as possible the nature and extent of exposure. The selection of appropriate biologic exposure indicators may be aided by intra- and

post-event environmental sampling. If the exposures occurred at an industrial location, additional information may be available through the company's environmental health and safety office or through the company's public reports submitted in compliance with the Emergency Planning and Community Right-to-Know Act.¹¹ Material data safety sheets are available online, as are databases such as the National Library of Medicine's toxicology databases. These are useful aids in choosing appropriate surveillance tests.¹² For radiological emergencies, useful resources include the Radiation Emergency Assistance Center/Training Site (REAC/TS) at the Oak Ridge Institute for Science and Education (available at: <http://www.ornl.gov/reacts/>). Resources for chemical exposures include local poison control centers, industry emergency response centers (many of which have 24-hour hot lines or online response), and federal agencies such as the Environmental Protection Agency. The Centers for Disease Control and Prevention maintains a registry of emergency preparedness training opportunities for clinicians, as well as information about biological hazards.¹³ Follow-up studies of clean-up workers at the World Trade Center demonstrate the importance of looking systematically for symptoms and biological indicators of exposure.¹⁴

Mental health issues are a critical component of worker safety and health management in disasters. Numerous studies have addressed the mental health consequences of disasters, and mental health professionals should participate in both pre-event planning and postevent management of workers involved in disaster response. There is still a need for considerable research related to the effectiveness of various mental health interventions used in disaster management.¹⁵ After the disaster, both emergency responders and those who worked at the location may require considerable preparation before resuming their work.¹⁶

Both occupational disease reporting and workers' compensation, although rarely immediate concerns in the postevent period, are considerations for workers who have been involved in disaster response. OSHA regulations require that employers report occupational illness and injury. Workers in a disaster may still ultimately be covered by OSHA regulations if the workers are responding as a part of their job.¹⁷ Similarly, many states have surveillance reporting requirements for occupational diseases, and in some cases, these could also apply to disaster response workers. Finally, workers who become injured or ill in the process of responding to a disaster may be entitled to workers' compensation.

OCCUPATIONS INVOLVED IN DISASTER RESPONSE

This section considers occupational groups that will typically be involved in disaster response. The experience of Sept. 11, 2001 showed that many individuals and volunteers may also be involved in disaster response, and their health needs should also be considered in the medical response; however, the groups discussed in this

section are, in many cases, expected to put themselves in situations in which they are likely to be exposed to potentially life-threatening hazards.

First Responders

First responders are primarily emergency and security personnel; the term “first receivers” has been used to describe those who are first to receive the victims in the emergency room. The overriding priority of first responders is to protect the victims and to secure the location. They rescue or otherwise protect others who are not able to save themselves. If the personal risk is acceptable, their secondary objective is to protect property from destruction or damage. To achieve these priorities, first responders allow themselves to be exposed to hazards that are unusual for anyone else in the community and that would not be tolerated in other occupations.

The occupations normally considered among first responders include the following:

- Police
- Firefighters (often cross-trained as emergency medical services [EMS] and hazardous materials [HazMat] personnel)
- EMS personnel

Two other categories of workers who are often deployed early in disaster response have been termed “second responders” and “skilled support personnel.” Secondary responders include a broad range of workers, including certain emergency public health and medical personnel, HazMat personnel, crime scene technicians, urban search and rescue personnel, mortuary personnel, radiation safety experts, structural engineers, and others who may be involved in all aspects of the disaster response. Skilled support personnel are defined in the HAZWOPER standard as workers who are operators of certain heavy equipment, such as hoisting equipment and cranes and earth moving or digging equipment, and who may also be exposed to hazards on-site.

First responders are generally the second to arrive on the scene after concerned nearby passersby and neighbors who rush to provide immediate assistance. In so doing, they are often exposed to hazards that would be intolerable in normal work. In a terrorist event, they would also be intentional targets.

The occupational risks of first responders include the same hazards that threaten the victims. Because first responders often arrive before the site has been secured, decontaminated, or thoroughly searched, they may face threatening situations on arrival. For example, the first arrivals at the site of a terrorist bombing must face the real possibility of a second explosive device intended for them. Even after the site is secured, first responders are confronted with events and circumstances outside the usual experience of humans in their daily lives.

Although each of the occupations that constitute first responders has its own set of hazards, risks, and traditions, first responders share several features in common, including:

- An awareness of personal danger, often accompanied by coping mechanisms that may include denial
- Long periods of relative quiet or routine interrupted abruptly by periods of intense activity, often accompanied by psychological stress
- Rigid codes of behavior and high expectations for performance, often accompanied by complicated job responsibilities and guidelines and high penalties for failure
- A strong ethic of teamwork and camaraderie, always with a strong sense of mutual reliance and social penalties for letting down one’s co-workers
- A rigid hierarchy or “chain of command,” which is necessary to reduce uncertainty and to make sure that procedures are followed correctly

Firefighters

Occupational hazards experienced by firefighters may be categorized as physical (mostly unsafe conditions, thermal stress, and ergonomic stress), chemical, and psychological.^{18,19} The level of exposure to these hazards that a firefighter may experience in a given fire depends on what is burning, the combustion characteristics of the fire, the structure on fire, the presence of nonfuel chemicals, the measures taken to control the fire, the presence of victims requiring rescue, and the position or line of duty held by the firefighter while battling the fire. The hazards and levels of exposure experienced by the first firefighter to enter a burning building and engage in fire suppression, called “knockdown,” are different from those of the firefighters who enter later to search for smoldering fuel that could flare up later, a process called “overhaul.” In general, the former is exposed to a greater risk of trauma, and the latter is exposed to more hazardous chemicals by inhalation.

There are many physical dangers in firefighting that can lead to serious physical injury.²⁰ Injuries can be minimized by intensive training, job experience, strict pre-placement screening, competency, and physical fitness. However, the nature of the job is such that firefighters may be placed in dangerous situations by miscalculation or circumstance or during rescues. The structure that a firefighter enters is not only on fire but often weakened structurally. Walls, ceilings, and floors may collapse abruptly and trap firefighters or cause them to fall. Exposed wires may present a risk of electrocution.

Injuries associated with firefighting are therefore predictable: burns, falls, and being struck by falling objects. Mortality from these causes is markedly increased among firefighters compared with other workers. Jobs in firefighting with a high risk of burns, especially, include those involving early entry and close-in firefighting, such as holding the nozzle. Burns are also more commonly associated with basement fires, recent injury before the incident, and training outside the fire department of present employment. Falls tend to be associated with self-contained breathing apparatus (SCBA) use, ladder work, and assignment to truck companies.

The energy requirements for firefighting are complicated by the severe conditions encountered in many inside fires. The metabolic demands of coping with retained

body heat, heat from the fire, and fluid loss through sweating add to the demands of physical exertion. Firefighters adjust their levels of exertion in a characteristic pattern during simulated fire conditions, as reflected by heart rate. Initially, their heart rate increases rapidly to 70% to 80% of maximal within the first minute. As firefighting progresses, firefighters maintain their heart rates at 85% to 100% of maximal.²¹

Firefighters exert themselves to maximal levels while battling fires. Climbing an aerial ladder, dragging hoses, carrying the traveling ladder, rescuing victims, and raising the ladder are among the most strenuous tasks, in declining order of energy demand. The most demanding activity is building search and victim rescue by the “lead hand” (first firefighter to enter the building), resulting in the highest average heart rate and highest rise in rectal temperature. Serving as “secondary help” (entering the building at a later time to fight the fire or to conduct additional searches and rescues) is the next most demanding activity, followed by exterior firefighting and serving as crew captain (directing the firefighting, usually at some distance from the fire). Other demanding tasks, in decreasing order of energy costs, are climbing ladders, dragging hoses, carrying a traveling ladder, and raising a ladder.

During firefighting, core body temperature and heart rate follow a cycle over a period of minutes: they both increase slightly in response to work in preparation for entry, then they both increase more as a result of environmental heat exposure, and they subsequently increase more steeply as a result of high workloads under conditions of heat stress. After 20 to 25 minutes, the usual length of time allowed for interior work by the SCBA used by firefighters, the physiological stress remains within limits tolerable to a healthy individual. However, in extended firefighting that involves multiple re-entries, there is insufficient time between SCBA air bottle changes to cool off, leading to a cumulative rise in core temperature and an increasing risk of heat stress.

Obviously, burns and other thermal injuries are leading causes of injury to firefighters, although standard “turnout” gear is very effective in minimizing the risk of burns. “Flashovers” are explosive eruptions of flame in a confined space that occur as a result of the sudden ignition of flammable gas products driven out of burning or hot materials and combined with superheated air. Fire situations that lead to “flashovers” may engulf the firefighter or cut off escape routes. Hot air by itself is not usually a great hazard to the firefighter. Dry air does not have much capacity to retain heat. Steam or hot wet air can cause serious burns because much more heat energy can be stored in water vapor than in dry air. Fortunately, steam burns are not common. Radiant heat is often intense in a fire situation. Burns may occur from radiant heat alone. Firefighters may also show skin changes characteristic of prolonged exposure to heat.

Under fire conditions, these physical demands are complicated by the metabolic demands of coping with heat and loss of fluids. The combined effect of internally generated heat during work and of external heat from the fire may result in markedly increased body temperatures that climb to unusually high levels in an intense

firefighting situation. Half-hour interval breaks to change the SCBA are not enough to arrest this climb in temperature, which can reach dangerous levels in prolonged firefighting. Although essential, personal protection imposes a considerable additional energy burden on the firefighter, particularly the SCBA.

Heat stress during firefighting may come from hot air, radiant heat, contact with hot surfaces, or endogenous heat that is produced by the body during exercise but which cannot be cooled during the fire. Heat stress is compounded by the insulating properties of the protective clothing and by physical exertion, which result in heat production within the body. Heat may result in heat stress, with the risk of dehydration, heat stroke, and cardiovascular collapse.

Unusual exposures, such as intense exposure to the fumes of burning plastics, can cause severe lung toxicity, reactive airways disease (where none existed before), and even permanent disability. Ordinary firefighting may be associated with short-term changes similar to asthma, which resolve over days. This does not appear to result in an increased lifetime risk of dying from chronic lung disease. However, this generalization may not apply in individual cases in which there has been an unusually intense exposure.

More than 50% of fire-related fatalities are the result of exposure to smoke, rather than burns. One of the major contributing factors to mortality and morbidity in fires is hypoxia because of oxygen depletion in the affected atmosphere, leading to loss of physical performance, confusion, and inability to escape. The constituents of smoke, singly and in combination, are also toxic. The toxicity of smoke depends primarily on the fuel, the heat of the fire, and whether or how much oxygen is available for combustion. Only carbon monoxide and hydrogen cyanide are commonly produced in lethal concentrations in building fires.

Firefighters tend to judge the level of hazard they face by the intensity of smoke, and they decide whether to use an SCBA solely on the basis of what they see. This may be very misleading after the flames are extinguished. The SCBA is an effective personal protection device that prevents exposure to the products of combustion when used properly. Fire services routinely require the use of SCBA during overhaul, but individual firefighters may ignore the requirement and wear it only during knockdown.

There is no apparent correlation between the intensity of smoke and the amount of carbon monoxide or cyanide in the air. Firefighters may also be exposed to nitrogen dioxide, sulphur dioxide, hydrogen chloride, aldehydes, and organic compounds such as benzene, depending on the material involved in the fire.

Certain situations present more airborne hazards than others. Firefighters should particularly avoid smoking during the clean-up, or “overhaul,” phase, when burning material is smoldering and therefore burning incompletely because carbon monoxide is likely to be in the atmosphere. Synthetic materials are most dangerous during smoldering conditions, not in conditions of high heat. Concrete retains heat very efficiently and may also act as a “sponge” for trapped gases that are then released from

the porous material, releasing hydrogen chloride or other toxic fumes long after a fire has been extinguished. Polymeric plastic materials in building construction and furnishings pose particular hazards because they combust into toxic products. Acrolein, formaldehyde, and volatile fatty acids are common in smoldering fires of several polymers, including polyethylene and natural cellulose. Cyanide levels increase with temperature when polyurethane or polyacrylonitriles are burned; acrylonitrile, acetonitrile pyridine, and benzonitrile occur in quantity in temperatures greater than 800°C but less than 1000°C. Polyvinyl chloride has been proposed as a desirable polymer for furnishings because of its self-extinguishing characteristics due to the high chlorine content. Unfortunately, the material produces large quantities of hydrochloric acid when fires are prolonged.²²

The introduction of SCBA and other protective equipment within the last 20 years has created a much safer working environment for the firefighter. However, the added weight of the equipment increases the physical exertion required and may throw the firefighter off balance in some situations. The firefighter's typical "turnout" gear may weigh about 51 lb and imposes a high energy cost. The protective clothing also becomes much heavier when it gets wet. A 20% decrement has been found in work performance imposed by those carrying an SCBA, which is a substantial restraint under extreme and dangerous conditions.

Police

In a disaster, police will have several functions: (1) establishing and maintaining order at the scene; (2) protecting the safety of the population at risk in the vicinity of the disaster; (3) protecting the safety of other responders; (4) maintaining the integrity of the scene if a criminal investigation is involved; and (5) in many cases, assisting with rescue operations. In a disaster, one of the most important functions of the police is to maintain the security of the disaster scene from well-meaning volunteers who may inadvertently put themselves and others at risk. Although they are commonly the first or second to arrive on-scene, police officers may not necessarily have access to the same level of PPE as other first responders, and the nature of their work can make it more difficult to consistently use PPE. The nature of the police force is such that in some cases it may be challenging to ensure that all potentially exposed police officers participate in postevent medical management and follow-up.

EMS Personnel

EMS personnel include paramedics, emergency medical technicians (EMTs), and other prehospital care providers. These personnel treat approximately 22 million patients a year in the United States.²³ In addition, they are first responders to natural and manmade disasters and are a crucial component of the nation's disaster response system. Although prehospital care personnel have been operating in the United States for more than a century, it is only recently that the full range of risks associated with this work has been investigated. Recent research has

shown that the occupational fatality rate for this group is more than twice the national average²⁴ and that the rate of nonfatal occupational injuries and illnesses may be more than five times the national average^{25,26}; the rate of nonfatal injuries and illnesses among EMS workers exceeds the rates for police and fire personnel.²⁷ Because these risks are only now being recognized, EMS personnel and managers as well as town council members and mayors, are largely unaware of the extent of the dangers associated with the work.

Historically, the role of EMS was to provide on-scene treatment and then rapid transportation to a hospital.²⁸ This role has been evolving in recent years as EMS agencies have become more involved not only in disaster preparation and response but also in community health. One agency, for example, instituted a program that reduced the county pediatric drowning rate by 50%.²⁹ EMS agencies nationwide are becoming more involved in a variety of community health initiatives.^{30,31}

The organization of EMS services varies widely by jurisdiction. In larger cities, fire departments typically provide first responder services for critical calls; fire department personnel may have training that ranges between a few hours of basic instruction up to full paramedic training. In some jurisdictions, EMS agencies are private companies contracted by the municipality; in others, the fire department is responsible for EMS and provides either fire personnel on ambulances or hires civilian workers for the ambulances. In other jurisdictions, a municipally owned and operated "third service" is responsible for providing EMS. Finally, hospitals or even police departments may operate a local EMS agency.

There are an estimated 900,000 EMS workers in the United States; approximately 175,000 are full-time workers and 154,000 are paramedics.²³ Volunteers provide much of the nation's EMS.³² There are more than 40 different levels of prehospital providers in the United States.³² However, most EMS workers can be divided into two primary job classifications: basic life support personnel, such as EMTs, and advanced life support personnel, such as paramedics. Training requirements for these personnel vary by state, but in general, EMTs have approximately 300 hours of training and paramedics have about 1200 hours more than the EMT level. Protocols also vary by state and local jurisdiction.

On a day-to-day basis, the risks faced by EMS workers include musculoskeletal injuries from carrying patients, assaults, needlesticks, and transportation-related injuries (e.g., from ambulance collisions, helicopter crashes, and by being struck by moving vehicles on the scene of a call). The EMS worker may have to carry a heavy patient down (or up) multiple flights of stairs or over slippery surfaces. EMS workers respond to calls in areas that have high crime rates and enter homes where the occupants are under a great deal of stress. The risk of needlestick injury may be increased when patients require immediate treatment in areas with poor lighting or in the back of a moving ambulance. Transportation incidents have been shown to cause the largest proportion of fatal injuries; they also account for many of the most serious nonfatal injuries.

Psychological stress may be a significant risk factor for EMS personnel, but the short- and long-term effects are not yet well understood. It also is not known how EMS work may affect chronic conditions. Because EMS workers tend to be young and because these workers have a high turnover rate, there are no data on how EMS work may affect workers' risk of cardiovascular disease, cancer, or other conditions. In addition, little is known about the general health of the EMS workforce. Whereas police and firefighting agencies typically have strenuous physical standards and requirements, EMS agencies may have few, if any, such policies.

The availability of PPE is believed to vary widely by agency and jurisdiction. Although all EMS workers likely have ready access to surgical gloves and masks, anecdotal information suggests that many workers do not have access to helmets, rescue gloves, turnout gear, or heavy boots. This paucity of resources may exacerbate the risks faced by EMS workers during disasters.

Other factors that may contribute to increased occupational health risks among EMS workers during disasters include lack of disaster-related training, lack of disaster preparation among EMS supervisors, poor coordination and communication with other public safety personnel, and inadequate equipment. Although little is known about the specific occupational health effects of disaster responses and operations on EMS workers, it is reasonable to presume that a person in an occupation that is becoming more widely recognized as having among the highest rates of nonfatal injuries and illnesses on a day-to-day basis would be at even greater risk of injury during a disaster event.

Secondary Responders and Skilled Support Personnel

Although there are few studies of the exposures or health consequences experienced by secondary responders and skilled support personnel in a disaster, experience suggests they may be at risk for significant exposures, particularly because in some cases these workers receive less training and have less access to PPE than first responders.¹ It is critical that these workers receive adequate training and "real-life" drills before a disaster and that they participate in postevent medical evaluations and surveillance activities.

RECOMMENDATIONS

If one is to reduce the severity of illness and injury experienced by workers in disasters, one must consider every aspect of the disaster, including the inciting agent(s), the worker, and the physical and social environments in which the disaster occurs. In addition, there are steps that can be taken at every stage of the disaster—before, during, and after the event—to decrease injury and illness severity. Healthcare workers, in particular, need to be involved in every aspect of planning the response, offering guidance in training, providing input on selection of appropriate PPE, coordinating triage and transport of injured patients, and ensuring that the facilities

exist to respond in a timely fashion when a disaster occurs. It is particularly important to conduct medical surveillance to detect subtle population-based changes due to exposures that might not be detected in individual workers. Risk communication must be an integral part of any response plan.

Disaster Preparedness*

Mark E. Keim and Paul Giannone

To start early is easy going, to start late is breakneck.
Maori proverb

EVOLVING DEFINITIONS

To communicate effectively about disasters as an empirical endeavor, clear definitions of the specific terms must be used. Unfortunately, “no definition of disaster is accepted universally”¹; therefore, this chapter begins with a definition of terminology that will serve as a foundation for further discussion of preparedness. For the sake of clarity and external validity, this chapter adheres to widely held definitions but also remains selective of some definitions that are particularly meaningful within the context of disaster preparedness.

The definition of *disaster* now adopted by the United Nations² and the World Health Organization³ describes disasters as: “A serious disruption of the functioning of a community or a society causing widespread human, material, economic or environmental losses which exceed the ability of the affected community or society to cope using its own resources.” An event that does not exceed a society’s capacities to cope is classified as an *emergency*: “. . . a sudden and usually unforeseen event that calls for immediate measures to minimize its adverse consequences.”³ During disasters, in contrast to everyday emergencies, organizations have to do the following⁴:

- Quickly relate to more and unfamiliar groups
- Adjust to losing part of their autonomy and freedom of action
- Apply different standards
- Operate within closer-than-usual public health and private-sector interfaces

Emergencies and disasters also tend to be conceptually differentiated from catastrophes.

In a catastrophe, as opposed to a disaster, the following take place⁴:

- Most or all of the community built structure is heavily affected.
- Local officials are unable to undertake their usual work roles, and this often extends into the recovery period.
- Most, if not all, of the everyday community functions are sharply and simultaneously interrupted.
- Finally, help from nearby communities cannot be provided.

Communities and nations must therefore evaluate their own unique vulnerabilities and plan accordingly for this entire range of potential events.

Emergencies and disasters are thus part of a relative continuum of events that occurs when a population is both exposed to a “threatening event or potentially damaging phenomenon,” referred to as a *hazard*.³ When a vulnerable population becomes exposed to any particular hazard, there are “lives lost, persons injured, property damaged and economic activity . . . disrupted.”³ These events are defined as *risks*. Risk is the product of hazard and vulnerability. Thus, the disaster is defined by the vulnerability of the population to a hazard event and not by the mere fact of its occurrence.⁵ The functional impact is determined by the resources of the community and the community’s ability to use its resources⁶ (referred to as *capacities* or *coping mechanisms*). Many factors increase a person’s vulnerability to health emergencies and disasters.⁷ Poverty is the single most important risk factor for vulnerability: “The poorest people in the poorest countries are the most vulnerable—and it is vulnerability that kills.”⁸

Vulnerability to emergencies and disasters has two sides—the degree of exposure to dangerous hazards (susceptibility) and the capacity to cope with or recover from their consequences (resilience). Vulnerability reduction programs reduce susceptibility and increase resilience. Susceptibility to disasters is decreased by prevention and mitigation of emergencies.⁹ Resilience has two components: (1) that provided by nature and (2) that provided through the actions of humans. One example of resilience provided by nature is the manner in which porous soil may allow for more rapid drainage of floodwater as opposed to more occlusive soil types. One example of human actions that affect resilience may be the social order of society and how this organizational

*The material in this chapter reflects solely the views of the authors. It does not necessarily reflect the policies or recommendations of the Centers for Disease Control and Prevention or the U.S. Department of Health and Human Services.

structure may facilitate (or hinder) response and recovery. Resilience is composed of (1) the absorbing capacity, (2) the buffering capacity, and (3) the response to the event and recovery from the damage sustained.¹

As preparedness increases, the ability of the society to absorb the event and thus lessen adverse outcomes is augmented as a dependent variable of preparedness.¹ By increasing preparedness, we increase resilience, decrease vulnerability, and thus lessen the risk of disasters. In addition, effective risk-reduction activities strengthen the buffering capacity of a population to respond to everyday emergencies found in all societies, thus minimizing the change in an essential function for a given change in available resources.¹

Both predisaster and postdisaster public health responses to disasters may also be considered within a context of preventive medicine.¹⁰ Primary and secondary prevention represent activities taken before a disaster.¹¹ Primary prevention is done to prevent adverse events from ever occurring. For example, floodplain management in an area of frequent flooding may actually prevent future inundation disasters altogether. In secondary prevention, measures are taken in advance that will decrease or eliminate the impact of risks.⁷ It involves mitigation, “structural and non-structural measures undertaken to *limit the adverse impact* of natural hazards, environmental degradation and technological hazards,” as well as preparedness, “activities and measures taken in advance to *ensure effective response to the impact* of hazards...”² Finally, tertiary prevention activities occur after the disaster response and recovery, when actions are undertaken to minimize loss of life and damage and to hasten the return to predisaster normal functioning.

Recently, the overall approach to emergencies and disasters among nations has shifted from ad hoc postdisaster activities to a more systematic and comprehensive process of risk management that also emphasizes the importance of predisaster activities, including prevention, mitigation, and preparedness.⁷ Disaster risk management, including risk-reduction strategies, is part of a more comprehensive system of actions that include prevention, mitigation, response, and recovery from the tragic event, whether that event is an emergency or a disaster.

HISTORICAL PERSPECTIVE

The events of the past three decades have given birth to an understanding of the importance of disaster preparedness. The Guatemala earthquake of 1976 killed 23,000 people and led to the publication of multiple articles analyzing aspects of the international response.^{4,9} Postdisaster analyses of this and other subsequent large-scale disaster events revealed a strong case for multihazard disaster preparedness. During the 1980s, new concepts that were based on the notions of hazards and vulnerabilities evolved. These concepts were further validated during the African famine and the 1985 Mexico City earthquake. Governments of industrialized nations began to abandon their disaster relief approaches to

better reflect the new importance of preparedness. This growing awareness was bolstered by a growing body of disaster research; an increasing professionalism in the field that grew to include academic coursework; the development of manuals and standardized tools; a growing “response fatigue” among donor nations and organizations; and an economic appreciation of the cost-effectiveness of prevention and preparedness as weighed against extremely expensive response efforts. The growing burden of disasters on global health was becoming all too clear. During a 20-year period, natural disasters alone killed 3 million people worldwide, affected 800 million lives, and resulted in property damage exceeding \$23 billion.^{9,12} In response to this growing threat, the United Nations (UN) General Assembly declared the 1990s to be the International Decade of Natural Disaster Reduction (IDNDR) and called for a global effort to reduce the suffering and losses.

In May 1994, one major achievement of the IDNDR was the hosting of the World Conference on Natural Disaster Reduction, which resulted in the *Yokohama Strategy and Plan of Action for a Safer World: Guidelines for Natural Disaster Prevention, Preparedness and Mitigation*.¹³ One of the strategies within the Yokohama Plan of Action stated that “[the world] will develop and strengthen national capacities and capabilities and, where appropriate, national legislation for natural and other disaster prevention, mitigation and preparedness, including the mobilization of non-governmental organizations and participation of local communities.”

The Johannesburg World Summit on Sustainable Development plan of implementation further stated: “An integrated, multi-hazard, inclusive approach to address vulnerability, risk assessment and disaster management, including prevention, mitigation, preparedness, response and recovery, is an essential element of a safer world in the twenty-first century.”¹⁴

A more recent UN General Assembly resolution on natural disasters and vulnerability takes into account the outcomes of the WSSD and the role of the International Strategy for Disaster Reduction. It coordinated a review of the *Yokohama Strategy and Plan of Action* as a major goal of the Second World Conference on Disaster Reduction held in Kobe during January 2005.¹⁵

CURRENT PRACTICE

The Approach to Disaster Preparedness

“Emergency preparedness is a program of long term development activities whose goals are to strengthen the overall capacity and capability of a country to manage all types of emergencies and bring about an orderly transition from relief through recovery and back to sustained development.”⁹

To be most effective, a disaster preparedness program must be one component of an overall vulnerability reduction strategy and should not be implemented as an isolated project. As stated earlier, vulnerability reduction must also include activities for reducing susceptibility by way of prevention and mitigation.

Disaster preparedness should be guided by a range of principles to adequately protect communities, property, and the environment. To be most effective, the approach must be:

- Comprehensive¹⁶
- All-hazard¹⁶
- Multisectoral and intersectoral¹⁶
- Community based¹⁶
- User friendly
- Culturally sensitive and specific

A comprehensive approach entails developing and implementing strategies for different phases of the emergency management cycle (i.e., prevention/mitigation, preparedness, response, and recovery) in the context of sustainable development. These phases often overlap each other both in time and scope. The management of emergencies is a process that should be part of the normal development plan of every country.

A widely used international concept is that of sustainable development. Sustainable development is “development which meets the needs of the present without compromising the ability of future generations to meet their own needs.”^{16a} This concept has been around for a number of decades, starting with the Declaration of the United Nations Conference on the Human Environment at Stockholm from June 5-16, 1972. Principle 1 of this declaration stated: “Man has the fundamental right to freedom, equality and adequate conditions of life, in an environment of a quality that permits a life of dignity and well-being, and he bears a solemn responsibility to protect and improve the environment for present *and future generations*.”^{16a}

The 2002 World Summit on Sustainable Development plan of implementation reaffirmed sustainable development as a central element of the international agenda.

The all-hazards approach¹⁷ concerns developing and implementing emergency management strategies for the full range of likely emergencies or disasters, including both natural and technological, which also includes conflict-related hazards of terrorism and warfare.

The multisectoral and intersectoral approach means that all organizations, including government, private and community organizations, and traditional and informal leadership, should be involved in disaster preparedness. If this approach is not used, emergency management is likely to be fragmented and inefficient.³ The multisectoral and intersectoral approach will also help to link emergency management to sustainable development through the institutionalization of risk reduction and the use of its principles in long-term development projects.

The concept of preparedness at the community level is based on the premise that the members, resources, organizations, and administrative structures of a community should all form the foundation of any emergency preparedness program. As the saying goes, “All disasters are local,” meaning all initial disaster responses start at the local level. External assistance in emergency management may be expected, but it should not be relied on as the sole means of risk reduction.

These combined approaches will also help link risk reduction to sustainable development through the

institutionalization of emergency management and the use of its principles in development projects. The resulting program becomes the responsibility of all and is undertaken at all administrative levels of both government and nongovernment organizations. The program concentrates not only on disasters but also on sustainable development of the society as a whole. These elements should be created at community, provincial, and national levels. An inherent capacity for risk reduction at each of these levels is a precondition for effective response and recovery when an emergency or disaster strikes. Without these capacities, any link from recovery to development will not be sustainable.

Health Objectives of Disaster Preparedness

Objectives of preparedness for health emergencies have been offered as follows:

- Prevent morbidity and mortality¹¹
- Provide care for casualties¹¹
- Manage adverse climatic and environmental conditions¹¹
- Ensure restoration of normal health¹¹
- Re-establish health services¹¹
- Protect staff
- Protect public health and medical assets

The actions required to meet these needs can be grouped into the following four categories¹¹:

1. Preventive measures (e.g., building codes, floodplain management)
2. Protective measures (e.g., early warning, community education)
3. Lifesaving measures (e.g., rescue and relief)
4. Rehabilitation (e.g., resettlement, rebuilding)

Elements of Disaster Preparedness

Although the terms *preparedness* and *planning* are sometimes used interchangeably or redundantly, planning constitutes only one component of a comprehensive program of disaster preparedness. The elements of emergency preparedness typically include vulnerability assessment, emergency planning, training and education, warning systems, specialized communication systems, information databases and management systems, resource management systems, resource stocks, emergency exercises,³ population protection systems,¹⁸ and incident management systems.¹⁹

Processes of a Disaster Preparedness Program

Comprehensive disaster preparedness programs have been described to include the following processes^{3,9}:

- Policy development
- Vulnerability assessment
- Disaster planning

- Training and education
- Monitoring and evaluation

Policy Development

Policy development includes legislation that is normally developed by a national government and mainly relates to responsibility for emergency preparedness and special emergency powers. There is also a need for central government, provincial and community organizations, and non-government organizations to develop appropriate policies.

Policy is required to ensure that common goals are pursued within and across organizations and activities, to streamline rapid decision-making, to ensure that actions are legal, to protect people from liability, and to ensure that common practices are followed. Without agreed policies, there will be poor coordination, a lack of a unified direction, and poor results. Policy can take the form of legislation, decisions by executive government, inter-organizational agreements, or organizational directions.

Vulnerability Assessment

The vulnerability assessment identifies and prioritizes potential hazards that may affect a community and suggests where damage may occur and which aspects of the community should be modified to lessen vulnerability. The assessment will also identify local capacities or coping mechanisms. It also provides a baseline for recovery strategies, in that it will describe the “normal” state of a community. There are a number of possible ways of assessing vulnerability. The process for vulnerability assessment described here is a series of steps, each of which contains a number of techniques. For example, hazard identification, community and environmental analysis, and hazard description are some of the steps. In turn, there are a number of techniques for identifying hazards, for describing the people, property, and environment that the hazards may affect, and for describing hazards and recommendations for risk reduction. Keim and Rhyne²⁰ have quantified the preparedness quotient, P_Q , as an objective measure of disaster resilience. This metric of health-sector preparedness has also been factored into a broader assessment of vulnerability that also includes an engineering-based measurement of mitigation.

Disaster Planning

A disaster plan is an agreed set of arrangements for preparing for, responding to, and recovering from emergencies and involves the description of responsibilities, management structures, strategies, and resource and information management. Disaster planning is about protecting life, property, and the environment.

“Planning is more important than the plan.”

Mark Keim, MD

The written plan itself is only one outcome of the planning process. The planning process should produce the following:

- An understanding of organizational responsibilities in response and recovery

- Stronger emergency management networks
- Improved community participation and awareness
- Effective response and recovery strategies and systems
- A simple and flexible written plan

A FUNCTIONAL APPROACH TO DISASTER PLANNING

Although the hazards that cause disasters vary greatly, the potential public health consequences and subsequent needs of the population do not.¹⁷ For example, warfare, chemical releases, floods, hurricanes, and earthquakes all force people from their homes. Based on this knowledge, a jurisdiction can develop a plan around the function of finding shelter for the displaced with minor adjustments for the rapidity, scale, duration, location, and intensity of different hazards.

Regardless of the hazard, disasters result in 15 public health consequences and create 32 categories of public health needs. And not all public health consequences are completed by public health staff. For example, public works and other government agencies are also involved in the provision of safe water, sanitation, and shelter. Table 25-1 provides a listing of the public health consequences and population needs caused by all natural and technological disasters, regardless of the precipitating hazard.

A critical aspect of planning for the response to emergency situations is to identify all of these common functions, assign responsibility for accomplishing each function, and ensure that tasked organizations have prepared standard operating procedures that detail how they will carry out critical objectives associated with the larger functions.

Keim and Giannone²¹ invented the Automated Disaster and Emergency Planning Tool (ADEPT), which represents software-based technology for assisting public health officials with an easily accessible and evidence-based method for writing, exercising, and improving public health emergency operations and planning. ADEPT identifies all of the functions of public health emergency response according to each major hazard. The tool then guides the user in assigning tasks and performance indicators for each of these functions. It integrates widely held national and international standards for public health, emergency management, humanitarian assistance, continuous quality improvement, and incident management.²²⁻³²

COMPONENTS OF A DISASTER PLAN

Most disaster plans that use a functional approach consist of the following four basic components:

- A “basic plan” containing a statement of policy, assignment of responsibility, and concept of operations
- A “functional annex” or set of contingencies that organize tasks around the completion of objectives related to each critical function
- “Hazard-specific appendices” or reference tables that

TABLE 25-1 PUBLIC HEALTH CONSEQUENCES AND FUNCTIONS ASSOCIATED WITH ALL DISASTERS

PUBLIC HEALTH CONSEQUENCES	PUBLIC HEALTH FUNCTIONS
Common to all consequences	Resource management Mental health services Reproductive health services Social services Occupational health and safety Business continuity
Deaths	Mortuary care Social services Mental health services
Illness and injuries	Health services Injury prevention and control Epidemiology Disease prevention and control
Loss of clean water	Access to safe water
Loss of shelter	Shelter and settlement Social services Security
Loss of personal and household goods	Personal and household goods
Loss of sanitation and routine hygiene	Sanitation, excreta disposal, and hygiene promotion
Disruption of solid waste management	Solid waste management
Public concern for safety	Risk communication Public information Security
Increased pests and vectors	Pest and vector control
Loss or damage of healthcare system	Health system and infrastructure support
Worsening of chronic illnesses	Health services
Food scarcity	Food safety, security, and nutrition
Standing surface water	Public works and engineering
Toxic exposures	Risk assessment Population protection Health services Hazardous materials emergency response Occupational health and safety

provide additional detailed information applicable to the performance of a particular function in the face of a particular hazard

- Standard operating procedures and/or checklists that detail how responders will carry out the tasks related to each function

Training and Education

Training and education involve training public health personnel and community responders in emergency management skills and knowledge and informing the community of the actions that may be required during emergencies and how the community can participate in emergency management.

The following are objectives of training and education in emergency management:

- The community is empowered to participate in the development of emergency preparedness strategies.
- The community knows the appropriate actions for different types of emergencies and the organizations it can turn to for assistance.
- Emergency management personnel are able to carry out the tasks allotted to them.

There are a number of possible training and education strategies that are suitable for different audiences and purposes. Strategy selection should be based on need, audience, purpose, available time, and available money and other resources.

Training and education strategies may include the following:

- Workshops, seminars, formal education programs, or conferences¹⁶
- Self-directed learning¹⁶
- Individual tuition¹⁶
- Exercises¹⁶
- Pamphlets, videos, media advertisements, newsletters, or journals¹⁶
- Informal or formal presentations¹⁶
- Training of the public, from schoolchildren to professionals¹⁶
- Public displays or public meetings¹⁶
- Mentorship and temporary duty assignments

Monitoring and Evaluation

Monitoring and evaluation involve determining how well an emergency preparedness program is being

developed and implemented and what needs to be done to improve it. These can be applied to all processes of a disaster preparedness program.

The following four methods for monitoring and evaluating preparedness are described here:

- Project management
- Operational debriefing
- Exercises
- Systems analysis

Project management is a means of monitoring and evaluating during the implementation phase of a project and includes:

- Measuring the progress toward project objectives
- Analysis to determine the cause of deviations in the project
- Determining corrective actions

Operational debriefing uses the process of an after-action study or a discussion of lessons learned after significant or strategically important operations. These evaluation tools are generally conducted immediately after a disaster event, may not be based on statistical analysis, and are more descriptive in nature. In its simplest form, it may be a forum for discussion of what went right and what could have been done better to improve services.

Exercises are a common way of monitoring and evaluating parts of emergency preparedness programs. Exercises can be used to test aspects of emergency plans, emergency procedures, training, feasibility of coordination, communications, etc. The purpose of an exercise, and the aspect of emergency preparedness to be tested, must be carefully decided and fairly specific. An exercise should not be conducted with the purpose of testing an entire emergency plan or all aspects of training.

Some typical types of exercise include:

- **Operational exercises:** where personnel and resources are actually deployed in a simulation of an emergency
- **Tabletop exercises:** where personnel are presented with an unfolding scenario, asked what actions would be required, and how the actions would be implemented
- **Syndicate exercises:** where personnel are divided into syndicates to discuss and consider a given scenario, and the syndicate planning and response decisions are then discussed in an open forum

System analysis is used to study the various components of a preparedness program, searching for the existence of elements of the program that are assumed to be important by using objectives, checklists, and key questions for each element.³³ The national emergency profile and health policy are dealt with in general terms, whereas the element concerning technical and administrative organization is analyzed in greater detail.

Managing the Process of Disaster Preparedness

Whether developing and implementing an entire emergency preparedness program or conducting a vulnerabil-

ity assessment or emergency planning project, project management methods will be required.

There are three major phases of project management: project definition, project planning, and project implementation.²³ *Project definition* concerns the aims and objectives of a project, as well as its scope and authority. *Project planning* is the process of sequencing tasks to achieve the project objectives and to ensure timely project completion and efficient use of resources. It involves determining tasks, assigning responsibilities, developing a timetable, and determining resource allocation and timing. *Project implementation* consists of project performance, monitoring and evaluation, and taking corrective action.

In the late 1980s and early 1990s a reformation of management theory and structure occurred in American business. Continuous quality improvement (CQI) arose out of the careful and disciplined study of traditional management approaches by a group of separate but similar thinkers.²³ Certain key features are inherent to any CQI approach, regardless of its specific application. These features include the following:

1. Customer focus (or, in the case of disaster management, victim focus)
2. Statistical application of knowledge of variation
3. Focus on process
4. Design and redesign
5. A redefinition of leadership

A rich literature has since developed regarding the implementation of CQI in a wide range of settings in both the manufacturing and service industries, including healthcare.²³ "CQI applications have been particularly relevant to the emergency department, given the process-based focus of quality improvement and the fact that the emergency department is a process rich environment."²³ The same could also be said for all phases of disaster management, which are also process-rich.

CQI as Applied to Disaster Preparedness

To a large extent, disaster planners previously considered the end results of their work to be largely immeasurable. The victim's journey from impact to recovery, although subject to numerous measurements, had been considered to be largely an immeasurable process, particularly with regard to customer satisfaction, cost, outcome, and measurement.³⁴ This is an odd paradox in a field whose very essence concerns the nature of being able to measure quantifiable differences in public health as the course of the disaster event progresses or improves. Nonetheless, a body of literature is now developing that supports the application of measures of effectiveness for evaluation and monitoring of humanitarian assistance efforts.³⁵

Although certain protocols have always existed within the fields of emergency and disaster medicine, there nonetheless has been a substantial degree of freedom on the part of the individual practitioner to diagnose and treat patients according to the preferences of the individual practitioner. The movement toward

more clearly defined clinical pathways in medicine and other specialties represents part of the success of CQI principles. There are many examples of successful control of special cause variation through accepted treatment protocols, including the use of the principles outlined in the Advanced Trauma Life Support Course,³⁶ the Advanced Cardiac Life Support Course,³⁷ the Advanced Pediatric Life Support Course,³⁸ and, more specifically related to disaster management, the Sphere Project.²⁴

CUSTOMER FOCUS

In simplest terms, a customer is any person who is affected by a process or product. In terms of disaster preparedness and response, this definition includes “external customers,” such as communities and their societies, and “internal customers,” such as multisectoral first responders and relief workers and their respective agencies.

STATISTICAL APPLICATION OF KNOWLEDGE OF VARIATION

Understanding the implications of variation in process is a critical skill for the disaster manager. Common cause variation refers to naturally occurring, statistically predictable variations that are inherent in all processes. By applying statistical principles, one can determine the variations that are common causes in nature, which helps guide appropriate interventions to improve the system. Because of the lack of understanding of the basic principles of common cause variation, one of the most common problems is tampering with the system as a result of overinterpretation of data.²³ Special cause variation is a natural variation caused by events or circumstances that are nontypical and therefore not inherent in the process. Such special causes are often operator-dependent (caused by variation in individuals providing service within the system). This is particularly true in cases in which different operators provide the service through a process that is inherently different from that of other providers. At its essence, CQI in many respects is the simple application of the scientific method to cross-functional processes that results in a deeper and more fundamental understanding of disaster response and recovery.

FOCUS ON PROCESS

Any project or program, including disaster preparedness, has a series of inputs and processes that produce outputs, which result in outcomes. The inputs of disaster preparedness include people’s time and energy, people’s perceptions of vulnerability and emergency requirements, money and resources, and commitment and perseverance. The processes, in this instance, are those of disaster preparedness. The outputs include information on hazards and vulnerability; training; resource acquisi-

tion; organizations that are aware of their responsibilities in preparing for, responding to, and recovering from emergencies; commitment to an emergency plan; and enhanced emergency preparedness. The outcomes of appropriate and effective disaster preparedness are improved protection of life, property, and the environment and the ability to sustain development.³

Virtually all interactions in disaster preparedness and response require interdependent, cross-functional processes for their successful conclusion. It is precisely because the disaster event is a process-rich environment that the precepts of CQI hold so much promise for improvement of disaster medicine. As Deming first noted, 85% of bad outcomes arise from the process itself, whereas only 15% arise from faulty performance by the individual provider.²³ Given this fact, CQI attempts to improve processes and systems rather than focus on individual performance.

EMPHASIS ON DESIGN AND REDESIGN

Another of the key concepts in CQI is the emphasis on design and redesign. As Donald Berwick³⁹ noted, “Every process provides information by which that process can be improved.” This focus on process improvement is a dramatic change from the prior emphasis on outlier activity. In traditional after-action studies or reports, quality improvement is attempted by routing out “bad apples” and adverse events in disaster drills and exercises or anecdotally identifying “lessons learned” from one disaster response rather than by improving entire processes and systems. However, quality is more than the absence of adverse events; elimination of outliers in a system may have minimal impact on mean performance. Quality exists to the extent that value is added in the course of the process itself. This goal of CQI is best achieved when the focus is on analyzing the system in such a way that the entire performance curve can be shifted to the right, so that “average performance” improves rather than placing emphasis primarily on the outliers with bad outcome.

A REDEFINITION OF LEADERSHIP AND EMPOWERMENT

The founders of CQI proved that the “traditional” management approach had certain subtle, inherent, unavoidable, and predictable consequences.²³ The role of the traditional manager was to observe the system and provide feedback to the staff in the form of exhortation, reward, and control. CQI recognizes that the continuous redesign of the system must of necessity include the input of those responsible for providing service to the patient or customer. One consequence of traditional management systems is the development of what Paul Batalden⁴⁰ referred to as “functional silos,” (otherwise known as “stove-piping”), referring to the situation when units or subunits in the system operate separately without coordination. In effect, this creates artificial functional vertical silos in disaster management processes that are fundamentally horizontal in nature. As these vertical

silos occur, the processes of necessity become unlinked (this is usually readily apparent to the disaster victim or the field responder). For this reason, communities, planners, and responders should make an effective transition to collaborative management philosophy in which governance is shared, workers are empowered, and quality is a function of community outcomes and satisfaction. Like the humanitarian charter of the Sphere Project,²⁴ the Deming method of CQI is rooted in the principles of human dignity and potential.²³ This redefinition of leadership and empowerment of the community also provide for the element of stakeholderism, which has also been described as an essential guiding principle necessary for effective disaster preparedness.¹⁶

PITFALLS

Pitfalls of Disaster Management in General

In one study of past disaster management problems and their causes, the following problems were categorized¹⁰:

- Inadequate appraisal of damages
- Inadequate problem ranking
- Inadequate identification, location, transportation, and utilization of resources

Among 22 U.S. disasters in this study, 93 examples of inappropriate management activities were identified. Most disaster mismanagement problems occurred because managers did not know what all of the relief activities were or how they should be accomplished.¹⁰ Difficulties in disaster management also frequently involve breakdowns in communication and coordination.⁴¹ The people of the Caribbean have a saying regarding the frequently recurring themes of disaster mismanagement that occur, "Horses never step in the same hole in the road more than once ... Only people do." Many of the mistakes that we make in disaster response could easily be prevented through adequate preparedness and learning from past mistakes.

Preparedness as a Short-Term Activity

"In disaster-prone countries, constant preparedness is essential."⁵ To be most effective, a disaster preparedness program should be one component of an overall vulnerability reduction strategy and should not be implemented as an isolated project.⁹

Lack of Valid Assumptions and Knowledge Regarding the Disaster Phenomenon

"Proper planning and execution of disaster medical aid programs require knowledge of the types of disasters that might occur, the morbidity and mortality that might result and the consequent medical care needs."¹² Health decisions made during emergencies are often based on insufficient or unnecessary health aid, waste of health resources, or counter-effective measures.⁴² In addition, the very nature of disasters adds difficulty to empirical or prospective study. These high-profile events also tend to gain a high degree of public and personal attention. The

literature is therefore replete with inaccurate anecdotal case reporting, even though studies of disasters have identified variables that contribute to the potential for injury.⁴¹

Over-Reliance on External Assistance, Mobile Field Hospitals, and Specialized Surgical Teams

It has been the personal experience of the primary author as both a disaster victim⁴³ and as a disaster responder that "families, friends and neighbors search, evacuate and extricate their own in the aftermath of a disaster"⁴⁴ and that by the time external relief teams are functional on-site, a very large majority of the total dead have already died,^{11,45-47} or in the case of chemical contamination, victims often arrive at the hospital before undergoing any prehospital decontamination.⁴⁸ External emergency relief is, therefore, largely expensive, wasteful, and not particularly effective.¹¹ These types of medical relief operations have been referred to as the "second disaster."⁴⁹

In addition, response measures do not always lead to the most effective means of recovery. Disasters, such as hurricane Mitch in Central America, may additionally negate the accomplishments of a generation in human, institutional, and economic development and increase the already high dependence on external assistance and financing.⁵⁰ This does not imply that disaster relief should be abandoned, but rather that a more comprehensive and cost-effective approach to disaster risk reduction and management is needed.

Misuse of Disaster Exercises

Experience is the key to a successful disaster response. Unfortunately, disaster drills occur infrequently, may not test the plan and the participants effectively, and may create a sense of misplaced security.⁴¹ In addition, an exercise should not be conducted with the purpose of testing an entire emergency plan or all aspects of training.³

Problems in Disaster Planning

Standard disaster plans, when completed, are rarely used in operations because of the following:

- They are cumbersome. Disaster plans tend to be extremely thick, nonuser-friendly documents that fulfill legal regulations but do not address operational problems.
- Staff is often not trained on or even aware of a developed disaster plan.
- Health disaster plans are not integrated into the overall planning process. They do not easily fit into the national plans or work on the assumption that other external players or agencies will coordinate or support public health response activities when required.
- Disaster planning that integrates government regulations/requirements and best practices creates plans that are difficult to operationalize.
- There is a tendency to have a single disaster plan and to send the same disaster response regardless of the particular circumstances.³

In addition, there are many challenges facing public health planners as they strive to perform these tasks in an efficacious and cost-efficient manner, including the following:

- Many public health officials throughout the world have limited knowledge, experience, and time for developing, evaluating, or improving the quality of emergency operations plans.
- Plans must address a broad range of hazards and contingencies and tend to be a voluminous document that must also be user-friendly and easily accessible during the postdisaster phase.
- Public health response activities must be well-integrated with other government and nongovernment agencies and institutions and be based on scientific evidence.
- Existing models and guidance for emergency operation planning focus on plan content (or tasks) rather than the process (or management system) and lack clear indicators of performance and outcome or measures of effectiveness.

Overemphasis on Mass Casualty Care in Health-Sector Disaster Plans

In the past, health-sector disaster planning tended to focus inordinately on mass casualty care, including surgical and critical care,²⁰ even though these interventions have tended to play a small role in public health.⁴⁴

Poor Planning for Management of Human Resources

Rescue personnel are generally reluctant to ask for rest, food, and water breaks while victims are in need.⁴¹ This results in high levels of fatigue, thus hindering effective operations, worker safety, and even patient care. Many plans and preparedness programs do not take into consideration the need for employee rest periods, occupational health measures, and critical incident stress management for disaster responders. Personnel problems associated with the inevitable onslaught of well-meaning volunteers can also occur.^{41,51}

FUTURE OF DISASTER PREPAREDNESS

The future of disaster preparedness will depend on the maturity of disaster medicine and disaster management as an empirical science. As is the case with the practice of medicine, one universally applicable procedure or template is not applicable to all instances. The “cure” must be based on an accurate diagnosis and appreciation of the unique needs and resources of the population involved. However, there is now a large and ever-growing body of evidence with which to guide well-informed decision-making. Best practices, such as the Sphere Project minimum standards,²⁴ that are well implemented at the community level and that integrate all sectors may become more commonplace. Qualitative assessment and management methodologies, such as the preparedness

quotient, vulnerability indices, and CQI²³ programs, may provide models for further objectification of disaster preparedness. Computer-driven disaster planning and management tools, such as the Centers for Disease Control and Prevention ADEPT disaster planning software²¹ and the Pan American Health Organization SUMA Humanitarian Supply Management System,⁵² may further facilitate timely and rapid evidence-based decision-making among a wider audience. A more holistic approach to disaster preparedness within the context of a comprehensive strategy of disaster risk reduction may promote sustainable development on a global scale. This will all depend on the commitment of those now called to the task. Future generations may either admire our thoughtful investment or curse our selfish shortsightedness. The dividends of preparedness, though seldom realized today, often become tragically obvious tomorrow.

Policy Issues in Disaster Preparedness and Response

Eric S. Weinstein

At the intersection of public perception, science, the duty of government to act, and the rights of the individual sits public health policy. Guiding the paths of healthcare providers, bureaucrats, and patients is an ongoing collaboration to do the most good for the most people. Citations from the *Bible* and other ancient texts demonstrate meritorious efforts to reduce the spread of disease. Scholars are quick to point out the lack of appreciation of factual scientific knowledge through centuries of political maneuvering to regulate immigration, forcefully separate innocents to protect the fearful, and hide the unfortunately afflicted from view. This chapter discusses recent examples of public health policy in the light of individuals' rights and the science of public health threats.

THE ETHICAL VIEW FOR THE SCIENTIST

In our free, democratic society, policy makers tasked with the authority to protect the public's health must also consider the individual's civil and political rights of liberty, privacy, association, assembly, and expression.¹ No one argues against the need to contain the spread of an illness or reduce the threat to life and property damage by terrorism or a natural or industrial disaster. Gostin¹ writes that it is not improper to restrain the enjoyment of liberty, privacy, or property per se, but it is improper to do so unnecessarily, arbitrarily, inequitably, or brutally. This can take place when government acts against a threat that is not valid or not based on objective, reliable scientific knowledge. Protecting public health is difficult to do when an uncertain, evolving illness begins to affect individuals and there is limited technology and limited acquisition of dynamic relevant information. Many illnesses appear the same early in the course of the illness, and it is not until later that the diagnosis can be affirmed. Consider such an illness affecting dozens, hundreds, or thousands of people spread over continents, with fear mounting and governments pressed into acting immediately. It would be the government's burden to defend and rigorously evaluate the effectiveness of a public health measure adopted to contain and treat this mystery illness in real time. Certainly,

a known illness for which research has identified the agent, vectors, susceptible hosts with evidence-based diagnostics, treatment, and cost to society can be addressed by an effective public health policy. The challenge to a public health agency is to reach this familiarity with a new syndrome or toxidrome in short order.¹

The balance between the establishment and maintenance of health and the prevention or reduction of transmission of illness with subsequent inhibition or reduction of the individual's rights should follow the doctrine of least-restrictive alternative to reduce the risk or ameliorate the harm. Legal scholars can assume this role alongside public health authorities who are not versed in the ramifications of invasiveness, the intrusion of an intervention on the individual's rights, or the scope and selection of individuals to receive an intervention. The duration of the intervention should be proportionate to the desired effect, with ongoing review to reduce untoward effects that would limit an individual's rights.¹

A fair public health policy benefits those in need and burdens those who endanger the public's health. These policies should not discriminate against sex, ethnicity, or other demographic factors unless scientifically proven to be accurate and if applied evenly will achieve the intended outcome. A means to address perceived inequalities or lack of sensitivity to individual rights is due process. This check-and-balance opportunity of an individual to seek the decision of others assembled to independently determine the merits of a public health intervention in a timely manner may reduce any further effects of a misapplied policy or ineffective course of action. This unbiased informed decision can fashion redress to rectify any misapplication or unintended consequences of policies. This form of process improvement will achieve more appropriate future policy and build trust in government that permits justice to be served.² Unfortunately, time is of the essence when a public health agency is pressured to act against an unknown illness. Review during the course of the dynamics of the response to the threat can and should occur simultaneously to scale back any restrictions on individual rights as the science of the event is established.³ The uninformed public must trust government to achieve compliance with public

health policy as the event unfolds before a wary media. Careful discussions in an open forum will not only make it easier for the policy to be accepted and thus achieve the intended end, but also will help attract unknown individuals or groups to further the policy through their involvement in the process. The common good for the public as a whole can be met by the involvement of the community of individuals. Transparency flushes facts, quells rumors, and dispels myths. Protection of an individual's rights can be ensured if the creation of public health policy adheres to necessity of action through proportional, nondiscriminatory, and fair means.⁴

EVACUATION ORDERS: "YOU MAY WANT TO HEED THIS ADVICE FOR YOUR OWN GOOD"

As fate yields opportunity, the writing of this chapter began with the author under the voluntary evacuation issued for coastal South Carolina in response to the then-impending threat of Hurricane Charley (Aug. 13, 2004).⁵ New evacuation measures had been put into place after the infamous 1998 mandatory evacuation of the Charleston, S.C. area in advance of Hurricane Floyd. That evacuation distressed families in that some sat in traffic for 18 hours along a more-than-150-mile stretch along I-26 up to Columbia. At the time of Hurricane Floyd, roughly 1/7th of the S.C. population participated in the evacuation of the entire coastline, with Hurricane Hugo still fresh on most residents' minds.⁶ The public outcry after the flawed Hurricane Floyd evacuation enabled the retrospective science of disaster medicine to produce significant changes to the entire data-gathering process that a S.C. governor uses to declare a mandatory evacuation under state law.⁷ Exercises have proven that lane reversals, new highway construction, and strategic placement of hundreds of S.C. law enforcement officers and Department of Transportation workers in concert with computer-aided scenarios have been successful to reduce the time of evacuation to up to 10 hours, despite a surge of migration from at-risk coastal S.C. areas.⁸ Shortly after the Hurricane Floyd evacuation, honest assessments took place, with a subsequent increased fund of concrete data used to make the executive decision to issue a mandatory evacuation order. An evacuation order can cost a state millions of dollars, disrupt local economies dependent on tourism, and further decrease an already waning public trust. In an effort to make an evacuation easier, the 2003-2004 S.C. General Assembly voted to amend a 1976 law to allow the governor to order that traffic lanes be reversed so that all lanes in an evacuation area flow in one direction away from the evacuation area.⁹

AN OUTBREAK AND THE EMERGENCY MEDICAL TREATMENT AND LABOR ACT: PATIENT CARE ENSURED

The key to any containment strategy is for the local government executive to issue an emergency order or proclamation establishing a new set of operating proce-

dures for public health authorities, the healthcare delivery system, and other government agencies.¹⁰ If an outbreak is local, the county executive or county council would issue the order or proclamation through a well-defined process. If an outbreak is across counties, the governor would issue the order or proclamation. The Emergency Medical Treatment and Labor Act (EMTALA) of 1986 permits regionalization of prehospital care to afford the best possible medical care for victims of trauma; those suffering from an acute cerebrovascular accident (CVA); and patients requiring special services such as pediatrics, obstetrics, and, increasingly, psychiatry. Under an executive order to mitigate the threat of a public health emergency (PHE), patients who meet predetermined criteria developed in a collaborative effort using the most accurate; timely; and, if possible, evidence-based determinations can be directed to an established healthcare facility (HCF) or a newly created facility staffed with the necessary personnel, equipment, and supplies to meet the need.¹¹ This plan can be accomplished ahead of time in anticipation of an outbreak of known pathogens or in the early phases of a new illness pattern detected through the triggers of syndromic surveillance.

Patients who enter the healthcare system after a telephone call to 911 (or other phone number) for emergency medical transport may be evaluated by an emergency medical technician (EMT) when the ambulance arrives. Currently, certain systems will permit an EMT-paramedic (EMT-P) evaluation for appropriateness of transport via emergency medical services (EMS). This is based on strict criteria developed by off-line medical direction; approved by county officials with appropriate documentation; and, more importantly, communication between the EMT crew, on-line medical control, and subsequent review of each call.¹² In a PHE, the most practical extension of this on-scene or field triage process is for an EMS crew, with an EMT-P, registered nurse (RN), or midlevel provider (physician assistant or nurse practitioner), to perform an evaluation of the patient for preset criteria. These criteria can be determined de novo as the PHE is evolving by the assembled collaborative team process or from prior known, reviewed, and learned outbreak responses. This process must include appropriate education about the outbreak; issuance of equipment, supplies, and personal protective equipment (PPE) to the EMS responders; and a screening process to exclude responders who may be more susceptible or less-than-adequate, placing them more at risk.¹³ The patient will enter the PHE evaluation and treatment process, and anyone else at the EMS evaluation site must be considered a contact person and enter the PHE evaluation process. The evaluation site must be assessed for epidemiological concerns and adjudicated accordingly.¹³

The dispatch of this PHE field evaluation team (FET) can be accomplished through use of priority medical dispatch or a similar 911 operating system. In a PHE, a person who calls the 911 system (or another telephone number for ambulance service for those regions not yet using 911) will undergo caller interrogation specific for the symptoms and any other information that can be learned. The caller will then be given instructions on

first aid for laypersons or the establishment of containment strategies pending arrival of the FET. Priority medical dispatch or a similar system can then send the FET to the scene to perform the evaluation, separate from the usual standard EMS.

If this evaluation determines that the patient is a potential victim of a PHE, the EMS crew can transport the patient to a HCF established to evaluate and treat the presenting symptom complex. If the patient is in distress, he or she will be attended to as per standard operating procedures and then transported to the HCF.¹¹ The EMS crew will be told what containment strategies and procedures an HCF has undertaken for the patient. During the executive declared PHE, the destination HCF may not be a standard HCF, such as the closest hospital, but it may be a “fever hospital” or an HCF specifically created for the PHE.¹³ This location will have healthcare workers (HCWs) who are trained, equipped, supplied, and donned in appropriate PPE. It may be on the grounds of the closest hospital, public health clinic, or in another building with appropriate air exchanges, water, heating and air, food preparation, restrooms, showers, etc. in the community to contain the PHE while allowing other hospitals and HCFs to attend to their usual patient loads without an influx of patients with special needs that may be incapacitating due to the surge in volume or contamination.¹¹ In a short period, such an unconventional HCF can be fully operational with prepositioned stores or vendor agreements.

Guidelines can be created, extensively reviewed from the go-forward, and adapted as the outbreak proceeds. If a patient is determined to meet predetermined criteria, then the process will continue with the patient discharged home with close monitoring, to another HCF for long-term care, or to another HCF for containment.³ If the patient does not meet the criteria, then the patient can receive appropriate diagnosis and care at that location and then be transported to an acute-care HCF (hospital, clinic, or physician office) for further evaluation, care, and discharge.¹⁴ The vehicle used to transport the patient and the accompanying personnel will have to undergo containment strategies from the initial PHE HCF to the next location.

EMTALA requires that the dedicated emergency department (ED) of an HCF perform a medical screening examination (MSE) for patients who present asking for a medical evaluation or when the MSE is requested by another person.¹⁵ Patients who self-refer to the ED during an executive declared PHE could receive an MSE by the hospital designated RN or midlevel provider donned in appropriate PPE. This HCW can be screened to ensure that he or she is fit for the assignment, vaccinated accordingly, and in-serviced to the threat at hand.³ The patient may receive an MSE, accepted by the physician at the PHE HCF, and sent with the appropriate EMTALA transfer documentation. If the patient requires stabilization before transfer to the PHE HCF or requires admission to the HCF for acute- and/or long-term care, this could commence accordingly, with containment strategies observed.

At the HCFs, containment strategies should include training of all employees to the specific presenting symptoms and signs of the PHE, use of PPE for those who rou-

tinely meet and greet people at their work stations, and limitations on entrance locations to the public.³ HCF-designated HCWs positioned to act as screeners can direct people entering the HCF to a receiving area for a more rigorous evaluation, separate from the ED, if they are coming to the HCF as a visitor or to conduct other business. More importantly, if a patient seeking medical attention enters the HCF through a nontypical entrance, containment strategies can commence accordingly. Signage specific for the PHE can direct patients presenting to the HCF for evaluation to containment areas designed for this initial evaluation.

It is plausible for specially trained HCWs, in tandem with personnel from law enforcement, public safety, department of transportation, or another like agency, to assist in the sorting of patients that self-refer to the HCF at locations removed from the entrance of the HCF. To reduce drunk driving for the public good, law enforcement personnel currently set up road blocks, at which they check driver’s licenses, registration, and insurance cards and screen for impaired drivers or passengers or vehicles suspected of being involved in illegal activities.¹⁶ An executive PHE can extend certain powers to law enforcement to assist the public health effort to contain the illness.¹⁷ Queues of traffic at locations safely established in route to a hospital can act as a checkpoint for screening, as previously noted, with direction of patients to the PHE HCF or their usual HCF containment area for an MSE. The vehicle and person(s) in the vehicle will enter the epidemiology evaluation and containment process. If the PHE HCW screening determines that a person fits the PHE symptom complex, the PHE FET can be deployed to conduct further evaluation and transport. The vehicle that carried the patient(s) will then have to be isolated, evaluated for contamination, and decontaminated accordingly.

SMALLPOX VACCINATIONS: THINK BEFORE YOU ACT

The Centers for Disease Control and Prevention (CDC) Advisory Committee on Immunization Practices (ACIP) revised its 1991 recommendations in June 2001 to include the use of vaccinia vaccine if the smallpox (variola) virus was used as an agent of biological terrorism or if a smallpox outbreak were to occur for another unforeseen reason. This plan included pre-exposure vaccination for first responders or treatment teams dispatched to attend to those exposed.¹⁸ Modlin¹⁹ was chair of the ACIP when the 2001 recommendations were released, and he later wrote a cautious editorial in March 2002 asking that policy makers weigh the best available analysis of vaccine-related morbidity and costs against the best available assessment of risk for smallpox release. Fauci²⁰ followed with similar caution, with a reminder of why the smallpox vaccination program was discontinued in the face of known risks, known transmissions, and known cases worldwide—there were several vaccine-related deaths each year as the risk of contracting the disease continued to decline. He concurred with the “ring-vaccination” strategy, which worked during past

decades and involves isolating those suspected or confirmed of being infected with the virus and then tracing contacts and their contacts for vaccination. This minimized the risk of adverse vaccine events (AVEs) and effectively used limited vaccines and other resources, including manpower to adjudicate the plan.²⁰

A widespread vaccination program is estimated to produce 4600 serious AVEs and 285 deaths.²¹ These numbers are unacceptable to many who are facing no known risk and no substantial proof of smallpox outside of known repositories.^{22,23} Meltzer,²⁴ through the CDC, in December 2001 showed that the number of susceptible persons and the assumed rate of transmission are the most important variables influencing the total number of smallpox cases to be expected from an intentional release of smallpox into a community. Data analysis of known outbreaks showed that one infected person would subsequently infect fewer than three persons; these data are important when deciding strategies of containment. The data showed that the ring-vaccination surveillance-containment strategy would yield the fastest time to contain an outbreak with the least number of deaths, but they did not discuss AVEs, the effect of smallpox morbidity, or the costs to adjudicate the strategy.²⁴

Non-peer review medical journals began detailing reservations about the National Smallpox Vaccination Program (NSVP) within weeks of its announcement. In preparation for the program's Jan. 24, 2003, commencement, hospitals openly questioned the financial burden of prescreening examinations, administering the vaccines, monitoring employees for AVEs, and providing treatment if necessary to the intended 500,000 first responder HCWs. They were also concerned that the risks of such a large-scale program for an unsubstantiated rumor based on loose "what-ifs" could reduce an already short staff because vaccinated workers may have to miss work. Hospitals also noted the risk of their HCWs transmitting vaccinia to patients in their facilities as well as HCW family members. Public health policy in this instance did not address the legal ramifications of compensation to inoculated HCWs who suffered an AVE, temporary or permanent. Who should pay the HCW if he or she cannot work? Would subsequent medical costs be paid through workers' compensation or an HCW's own medical insurance?²⁵ These questions still have not been answered.

The Homeland Security Act of 2002 extended liability protection to the manufacturers of the vaccine, hospitals administering the vaccine, and individuals receiving the vaccine, presumably if they transmit vaccinia to another person. Hospital attorneys debated what locations were protected because it appeared that hospitals themselves were protected only if their vaccination clinic was on-site but not if they chose an off-site HCF such as a clinic.

Reports of HCW AVEs were accumulating with the commencement of the NSVP, slowing the program to a trickle. If 30% of HCWs in some facilities would have had to miss some work, the staffing nightmare could have been dangerous. In April 2003, the CDC ACIP released a supplement, *Recommendations for Using Smallpox Vaccine in a Pre-Event Vaccination Program*, to its 2001 smallpox vaccine recommendation, moving

the focus from each hospital establishing and maintaining at least one response team to only the state having a team. The acquired knowledge of AVEs supported vaccinating healthy, screened HCWs who had been previously vaccinated to staff HCF treatment teams. Dressings to cover the vaccination site, changed by a specific team, were stressed, as was vigorous handwashing techniques. The pre-NSVP concern about administrative leave was not required unless specific minor AVEs developed. The CDC released preliminary reports²⁶ of 10 cases of myopericarditis among approximately 240,000 healthy personnel who received the vaccine for the first time and none among 110,000 who received another vaccine as a booster. The report noted two civilian volunteers with AVEs (one with myocarditis and one with pericarditis), a rate greater than what was previously noted in unvaccinated healthy military personnel from 1998 to 2000. More disturbing were the reports of five civilian volunteers who contracted myocardial ischemia-related AVEs, three with infarction and two with angina. Screening noted that four of these five had known cardiovascular risk factors, and the other had known cardiovascular disease.²⁶ Based on these findings, the CDC ACIP released another supplement, this time excluding persons with cardiac disease or risk factors from the NSVP.²⁷

Sepkowitz²⁸ answered the question: How contagious is vaccinia? The research showed a risk of secondary transmission of vaccinia, with an 11% fatality rate, with nosocomial transmission apparently occurring through minor contact with a source case. Incidental transmission in the home was noted to occur more often with sustained, intimate exposure that is believed to be related to differences in immunological competency and dermatological differences. With the recommendation to not grant administrative leave for newly vaccinated HCWs, hospitals would have to weigh the risk of a self-inflicted epidemic for an unrealized, unsubstantiated risk.²⁸ Data gathered from January to July 4, 2003, did not corroborate the conclusions of Sepkowitz's study; there were no transmissions of vaccinia from 37,875 vaccinated volunteer civilians to other persons.²⁹ These uncertainties of benefit versus the reduced risk combined with the end of the conventional war in Iraq without finding any evidence of weapons of mass destruction and a contentious medicolegal climate in the United States contributed to a less-than-enthusiastic response to the NSVP.

More than a year after the commencement of the NSVP, policy makers showed HCW who volunteered to be vaccinated that they were listening to their concerns by passing the Smallpox Emergency Personnel Protection Act of 2003 (Dec. 13, 2003).³⁰ Funded at \$42 million, the program provides financial and medical benefits to eligible members of a smallpox emergency response plan approved by the U.S. Department of Health and Human Services (HHS) who sustain certain medical injuries caused by a smallpox vaccine. In addition, unvaccinated individuals injured after coming into contact with vaccinated members of an emergency response plan—or with a person with whom the vaccinated person had contact—may be eligible for program benefits. The program also

provides benefits to survivors of eligible individuals whose death resulted from a covered injury. HHS recognized the disconnect from the NSVP felt by HCWs when it began implementation of the compensation program by publishing a Smallpox Vaccine Injury Compensation Table in the Aug. 27, 2003 edition of the *Federal Register*.³¹ The table became effective upon publication. Moving this from HHS to federal law only contributed to the loss of public faith in the program.

Bozzette and others³² posted *A Model for Smallpox Vaccination Policy* on the *New England Journal of Medicine's* Web site on Dec. 19, 2002. This stochastic model of outcomes considered a range of threats, including a hoax, and predicted the number of deaths, but not morbidity nor the extent of AVEs, after the use of various measures to contain the spread of smallpox. The study brought policy implications to the forefront, specifically the benefit of isolation while highlighting the lack of case law with concerns of denial of civil liberties.³² Federal law gives the U.S. Public Health Service the power to detain individuals, for such time and such manner as may be reasonably necessary, believed to be infected with a communicable disease in the communicable stage to prevent transmission of the disease.³³ Containment strategies have been successful for centuries to combat the spread of smallpox. Smallpox is spread via large droplet respiratory transmission from face-to-face contact. In 1988 the World Health Organization determined that air samples taken in the vicinity of smallpox patients were rarely positive. This, coupled with the observation that most patients with uncomplicated disease are not capable of generating a strong enough cough to propel aerosols long distance, builds the clinical case for smallpox containment strategies.³⁴ Containment vaccination can be directed at the persons at the highest risk for disease—those who had face-to-face contact within 2 meters.³⁵

CONTAINMENT STRATEGIES: LIMIT CONTACT, LIMIT THE SPREAD

Barbera and colleagues³⁶ published a primer on the containment strategies of quarantine (potentially exposed to an infectious agent) and isolation (suspected infection determined by the manifestation of the agent's symptoms/signs/laboratory confirmation). The term *large-scale quarantine* was defined to assist public health policy planners to distinguish a few patients potentially exposed from the numbers that policy planners envision in bioterrorist scenarios or a pandemic.³⁶ This clinical strategy is no different than the commonplace school or work excuse that physicians provide ED patients, but on a grand scale to limit the spread of an infectious agent from others. A physician writes an excuse, and the school or employer recognizes that the physician wants to protect the other students or employees from "catching" the illness. The student or employee suffers no consequence or injury from not attending school or showing up for work. Individual citizens appreciate the need for government to prevent significant risk to the health of themselves and others. The public health con-

tract between the individual and the government cedes certain rights and liberties to achieve a healthier and safer society. A federal statute applies to interstate commerce or travel between states or countries, whereas a state statute applies to most all other instances that would require compulsory separation of individuals. The framework for public health powers (necessity, effective means, proportionality, and fairness) must be applied to the draconian police powers of quarantine and isolation through the following questions¹:

1. Does the science of the known infectious disease process support the separation of those infected or those possibly infected from those not infected?
2. Can those separated be placed into quarters that will not further the infectious process, respect their dignity, and provide reasonable levels of comfort?
3. Does the risk of separation of individuals from their families, livelihood, and communities outweigh the risk of not separating them and thus furthering the disease among their families, workplace, or communities?³⁶

SCIENCE CALMS FEARS

Smallpox is not transmitted during the prodromal phase of high fever that precedes the rash. If an individual is exposed to smallpox, he or she can be quarantined to his or her home and can maintain most levels of normal activity until the start of a fever. Then, these individuals can be isolated until it is clear that the fever is not from smallpox. A close contact of a documented smallpox patient should receive the smallpox vaccine if there are no contraindications. If the exposed person is unwilling to accept the risk of the smallpox vaccine or is found to have contraindications, then a full 18-day quarantine is warranted to observe for the tell-tale sign of fevers. The contact is then isolated to reduce the transmission of smallpox to others, with the possibility of vaccination increased since the prodromal now has smallpox or, if the vaccine is contraindicated, other therapies can be administered. This would be the least-restrictive alternative to permit observation without complete disruption of the individual's life and those that depend on him or her.³⁷

SEVERE ACUTE RESPIRATORY SYNDROME: REAL-TIME SCIENCE INTERSECTS WITH DIFFERENT GOVERNMENTS

Canada

Dwosh and colleagues³ showed clear evidence of swift strategy to contain the severe acute respiratory syndrome (SARS) virus at the Richmond Hill Hospital (Toronto, Canada) in March 2003. Patients and hospital staff who had come into close, unprotected contact with two index SARS patients were identified and told to stay home and monitor themselves for a list of symptoms and signs with calls twice a day from public health officials. Fifteen people who began to exhibit the first signs of the illness,

specifically a fever, were then isolated. Thereafter, no further cases of SARS were identified.³

China

In May 2003, 1 month after the SARS outbreak had peaked, people in the Haidian District of Beijing who had close contact with a suspected SARS patient for more than 30 minutes' duration were quarantined. At first, quarantine lasted for 14 days and was later reduced to 10 days and then 3 days as the results of quarantine strategy were reviewed. A least-restrictive alternative for travelers entering the area was personal surveillance with close medical supervision to permit prompt recognition of infection or illness without restriction of movement. Only persons who had a history of contact with a SARS patient developed SARS during quarantine. In contrast, none of the people who did not come into contact with a SARS patient developed SARS. There were no cases of secondary transmission of SARS to relatives or other contacts during quarantine. Exposed persons were sent home and told to monitor their temperature and to have all members of the household observe strict handwashing precautions and to use respiratory masks. Review of the data showed that if public health authorities had focused only on persons who had contact with an actively ill SARS patient, the number of quarantined persons would have declined by 66%. Persons exposed to a SARS patient in the incubation phase had little to no risk of contracting SARS. It was determined that a person exposed to a SARS patient could monitor his or her temperature alone while on personal surveillance with public health monitoring. If the person developed a fever, then he or she would be removed from the home and isolated. Such modifications would have returned persons to their routines more promptly and reduced the overall resources spent to observe patients in their homes. As the illness is identified as a separate entity through surveillance, data can be collected in real time to permit these changes on a more dynamic basis.³⁸

Taiwan

Taiwan public health authorities used different containment strategies; close contacts were quarantined for 14 days from February 2003 until June 10 and then aligned with the World Health Organization 10 days later. Hospital staff and patients in close contacts with SARS patients were quarantined in HCFs; all others were quarantined at home, except for homeless persons, who were asked to go voluntarily to government quarantine centers. This tiered system was extended to travelers to Taiwan from April 28 to July 4. Travelers were quarantined for 10 days in an airport transit hotel, at home, or at a quarantine site designated and paid for by their employer if under business (otherwise by the government). If one of these sites was not available, then the traveler was quarantined at a government center. On June 9, because of pressure from Taiwan business leaders, restrictions were eased for employees of Taiwanese companies based in mainland China who were returning to Taiwan for business. These travelers were allowed to return to work if they wore surgical masks.³⁹

Persons under quarantine were required to stay where they were quarantined, to wear masks, and observe other precautions, with frequent readings of their temperature. The differences in Level A quarantine (14 days, close contact) and Level B quarantine (traveler, 10 days) were restrictive and not based on science because a traveler could have just as easily come into close contact with a SARS patient and develop a fever as could an HCW or family member of a SARS patient. Yet the Level A person was not permitted to leave the site unless deemed necessary by public health authorities, with all meals delivered. Level B persons were free to go to an open area to exercise and purchase meals. To clearly show the difference in approach, Taiwanese officials used video monitoring of some persons who were contacts of a SARS patient and were found to have violated their quarantine at home. Due to this commonplace occurrence at the end of the outbreak, most at-home quarantine persons were under video monitoring. Persons who completed their quarantine received a payment of the equivalent of U.S. \$147.00 and other social services from local authorities.³⁹

Of the 131,132 persons quarantined, 286 (0.2%) were fined for violations of their quarantine. Of the 50,319 persons in Level A quarantine, 4063 (8%) were placed under video monitoring, and 112 developed SARS. Of the 80,813 persons under Level B quarantine, 21 (0.03%) developed SARS. Those with the highest risk of contracting SARS were exposed HCWs (0.34%), family members of SARS patients (0.33%), and those who were on the same airplane flight who sat within three rows of a SARS patient (0.36%). The lowest percentage of patients were those simply traveling from a SARS-affected area.³⁹

Hong Kong

On March 1, 2003, the spread of SARS in the Hong Kong Special Administrative Region was traced to Prince of Wales Hospital HCWs and their contacts. After slow implementation of internal containment strategies—specifically, isolation—the outbreak was slowed. The second wave of SARS was traced to a patient who used a toilet in a housing project, which led to that entire area being quarantined. This was worsened when persons from the affected housing project went to a nearby housing project, not observing quarantine or partially adhering to guidelines. The third wave inundated hospitals as the entire region was in the midst of the outbreak. By April 10, “home quarantine” was implemented for household contacts of confirmed SARS patients. The time lag to identify SARS patients led to a peak on April 17. It was not until April 25 that “home confinement policy” was extended to households with contacts of suspected SARS patients.⁴⁰

LEGISLATING PUBLIC HEALTH

The Model State Emergency Health Powers Act was enacted Dec. 21, 2001, to provide a framework for governors, legislatures, and public health officials to review their statutes and regulations to adhere to the following principles: preparedness, surveillance, management of

property, protection of persons, and communication.⁴¹ Gostin noted that the body of public health statutes is layered on old statutes implemented in response to a public health threat decades ago and that a review for current evidence-based medicine or a review grounded in sound science are unlikely. As medical theory has expanded with technology,¹ legal appreciation of an individual's rights have also been defined without benefit of public health law keeping pace. Old legal remedies may not apply to current public health dilemmas; insufficient authority may limit effective action; and coordination between local, state, and federal authorities may be hindered by conflicting statutes that have been rendered moot through technology.⁴¹ Coercive powers may be the only means to ensure the safety and health of the public and must not be taken lightly. Public health law gives government the authority to limit personal interests to safeguard the public health through powers bounded by necessity, effective means, proportionality, and fairness; in return individuals forgo autonomy, liberty, or property. The model act itself is divided into the pre-emergency environment for predeclaration powers and the powers that become the governor's to use after declaration of an emergency. The declaration of a public health emergency must meet the following criteria: (1) an occurrence or imminent threat of an illness or public health condition that (2) is caused by bioterrorism or a new or re-emerging infectious agent or biological toxin previously controlled that also (3) poses a high probability of a large number of deaths, serious or long-term disabilities, or widespread exposure to an infectious or toxic agent that poses a significant risk of substantial future harm to a large number of persons.⁴¹

The model act filters redundant statutes, removes statutes that have become irrelevant, and enhances traditional public health powers with an extensive set of conditions, principles, and requirements governing the use of personal control measures. Specific advancements include the use of home confinement or other creative less-restrictive alternatives for containment rather than compulsory isolation or quarantine and permits persons so contained to be afforded due process, appropriate medical care, activities, hygiene, and food.⁴¹ Transparency of communication with the public to explain protective measures and access to mental health will reduce public misperceptions. Immunity is afforded to persons exercising authority under the specific declarations of the governor. As of July 2004, 20 states had enacted laws along the model act guidelines of the 29 states that have introduced similar legislation.⁴²

Civil libertarians point out the evolution of public health powers, with the federal government retaining authority over interstate and foreign commerce, national defense, and the expenditure of money. Even with the creation of the Department of Homeland Security, the CDC still remains the lead advisory consequence agency in a PHE. In the event of a bioterrorist outbreak, the Federal Bureau of Investigations will provide federal crisis management that is coordinated with a state crisis management agency. In most states, the lead state consequence management agency lacks the depth required in current state law for basic public health to function appropriately.

Annas² stated that the model act should respond to real problems, but the scenarios that would require use of these powers are not known and are left to the transparency of the process of a state government to recommend to the governor to use in a PHE. These powers are for all biological agents and their toxins, regardless of entry into the public. Annual influenza epidemics, by definition, are a PHE with the full depth of the government prepared to prevent a pandemic. The fear and panic after the anthrax incidents in the fall of 2001 cannot be compared to the reality of a true PHE involving the deployment of community HCWs. There is no empiric evidence that certain containment strategies are unfounded.

THE DIRECTION FROM HERE

Civil libertarians and legal scholars are becoming more familiar with the science of outbreaks and other elements of public health threats. Scientists are becoming more astute in the ethical and legal ramifications of intended therapies and interventions. The synergy and collaboration between these guardians of public interest will increasingly contribute to the government's ability to formulate effective public health policy.

Mutual Aid*

James Geiling and Kerry Fosher

Disaster strikes, and first responders gather their resources, move to the scene, and begin to execute a well-rehearsed response. Personnel, supplies, and equipment meet the requirements of the operation, and once completed, they are refitted and resupplied for the next calamity. But what happens when the disaster evolves slowly over time and distance, involving many organizations across jurisdictional boundaries? Or when, given the just-described scenario of a sudden-impact disaster, local resources become rapidly depleted? Victims of disaster require and, whether in the form of a warm bed or a hot meal, these requirements may exceed the local resources.

Just as an individual who is baking a cake may need a cup of sugar from a neighbor, organizations responding to emergencies occasionally need the assistance of others. Mutual aid is one of the earliest and most organic forms of interagency cooperation and coordination in public safety and health services. Without prearranged mutual aid agreements, events that deplete or exhaust community resources jeopardize the health and safety of not only the victims directly affected by the disaster, but also the rescuers and emergency management personnel themselves.

This chapter introduces a brief history of the federal plan to support disaster response as it applies to working with state and local governments. The chapter also covers the basic concepts of developing mutual aid agreements; organizational leads at the local, state, and federal levels for developing plans; and two common pitfalls that undermine mutual aid plans and operations.

THE MUTUAL AID CONCEPT

Response, Recovery, and Regional Capacity Building

The mutual aid concept in its most basic form is simply the sharing of resources among organizations in times of

need. Mutual aid can provide an organization with personnel, equipment, supplies, and pharmaceutical agents in an existing or anticipated emergency. Mutual aid agreements serve to regulate the sharing process, with the identification of what resources can be shared and under what circumstances. Agreements also address potential problems, such as the liability of sharing organizations and responders, reciprocity of credentialing and licensure, the ability of the sharing organization to hold back resources to protect itself, and expectations regarding accounting and reimbursement.

Mutual aid agreements tend to be made between like organizations. Hospitals make them with hospitals, law enforcement agencies with other law enforcement agencies, utility companies with utility companies. Even libraries and museums have mutual aid agreements for coping with disasters.^{1,2} However, agreements also are made among jurisdictions, such as state-to-state or county-to-county mutual aid, covering a range of public safety, health, and public works organizations.

When most people think of mutual aid, they picture a cluster of fire trucks or ambulances from different jurisdictions at the scene of a disaster. Mutual aid for dealing with an emergency or a disaster is a very common arrangement, but the concept is not limited to response alone. Mutual aid agreements are often written to include recovery operations as well. These arrangements allow sharing of public works and administrative assets that might not be needed until the crisis has passed. In fact, there is nothing to preclude even pre-event mutual aid in the form of cooperative planning and training agreements, although this is currently rare.

Mutual aid for response and recovery has become part of the decision matrix for planners in many areas of the United States.³ As the technical base for response equipment and training expands, planners must make decisions about where to place specialized resources for the maximum value to the region. These decisions can be made more resilient through the use or development of mutual aid agreements that address how these regional assets can be shared. Resource placement can then be determined based on the best access to potential users who are partners in the mutual aid agreement.

*The opinions and assertions contained herein are those of the authors and are not to be construed as official or necessarily reflecting the views of the Department of Veterans Affairs or the United States Government.

Conceptual Planning Concerns

The use of mutual aid as a planning tool is very valuable for overall capacity building in a state or region. In times of fiscal constraint, many regions are not able to provide exactly equal resources in every area or in each facility. Good agreements allow planners to consider the capacity of the entire mutual aid network when choosing how to allocate resources for overall preparedness. Of course, this type of planning has always taken place on an informal level. Planners tend to know what other organizations in their area have available to share. However, the use of mutual aid agreements can systematize the process and make it more accountable, minimizing the chances of gaps or misunderstandings. As previously mentioned, most mutual aid agreements address issues of finance, liability, licensing, and the need for organizations to withhold aid based on judgments of their own vulnerability. More sophisticated agreements may also contain annexes of protocols to address common operational interests.

Most conceptual planning concerns are ultimately problems of definition, management, or sustainability. When an organization, such as a hospital, realizes it is overwhelmed, it usually requests mutual aid. However, this means that somebody has to decide what “overwhelmed” means and, hopefully, recognize that operations are approaching capacity in time for mutual aid assets to make a difference. Advance work to define what “almost overwhelmed” might look like in various scenarios goes a long way toward smoothing actual operations. Organizations must also work to “type” their resources, categorizing assets they can share or expect to receive based on the type of emergency. Requests made under mutual aid agreements may be easier to fulfill when requestors ask for a capability rather than a specific organization. Again, advance definition of resources can greatly facilitate the delivery of aid.

Plans to manage mutual aid must include how aid is dispatched, received, managed on-scene, and demobilized. Appropriate dispatch depends on the organization being able to make a considered and coherent request for resources. The receiving organizations must also have protocols for receiving the aid and incorporating it into ongoing operations. Finally, the receiving organization must understand how to demobilize human resources and return or dispose of material ones.

For many types of emergencies and for all disasters, sustainability is a critical element of response and recovery success. Mutual aid often can provide the resource “depth” for an organization or jurisdiction to sustain response until state or national assistance is deployed. Problems can arise if resources are requested too quickly and are exhausted or if they are recalled before they can be useful in extending the duration of response. Some mutual aid planners now want their agreements to include discussions of response sustainability and to provide guidelines to help those on-scene make sound judgments about response timeframes.

Under incident management, it becomes the responsibility of the incident command structure to handle whatever assets arrive through mutual aid. However,

incident management is only a system for regularizing the activities of the organization in an emergency or disaster. The system depends on good operational guidelines to ensure that the only unpredictable element in the response is the disaster itself.

Groups such as the National Emergency Management Association and the American Hospital Association⁴ have developed model agreements for organizations, localities, and states to use when developing their own mutual aid agreements. A well-known example of this standardization trend is the Emergency Management Assistance Compact (EMAC), a template plan for state-to-state mutual aid.⁵ EMAC, described in more detail later in this chapter, is a national mutual aid system for states, but allows some tailoring to meet local needs. Currently, only two states, California and Hawaii, have not adopted the EMAC.

Although each agreement must be tailored to meet organizational and regional needs, the opportunity for standardization has benefits beyond saving keystrokes. In some cases, time and resources saved in creating the agreement can be used for training people to implement it, an element of mutual aid that is sometimes neglected due to other training priorities. Standardization can also help ensure that agreements address operational concerns and are consistent with national plans, such as the National Response Plan⁶ and the National Incident Management System.⁷

HISTORICAL PERSPECTIVE

Although discussed in detail elsewhere in this textbook, a brief review of the national disaster response history may provide a perspective on how mutual aid agreements and processes at differing government levels have matured over time. Recent disaster response organization in the United States at the federal level dates to the early 1960s when the newly formed Federal Disaster Assistance Administration of the Department of Housing and Urban Development managed several massive disasters. For example, after the Alaska earthquake of 1964 in which needs far exceeded available local resources, many questions arose as to the federal government’s capability to appropriately respond. Review of this disaster and others in subsequent years led to the establishment of a process for presidential disaster declarations through passage of the Disaster Relief Act in 1974. This act provided the legal processes under which state governors could formally request federal assistance after disasters for support that exceeded the state’s response capabilities.⁸ It was, in essence, the first state-federal government, disaster-specific mutual aid agreement.

However, disaster response at the federal level remained fragmented. More than 100 federal agencies could be called on to respond to disasters ranging from natural events to accidents involving the transportation of hazardous materials.⁹ In 1979, President Carter issued Executive Order 12127, which merged many disaster-related responsibilities into the Federal Emergency Management Agency (FEMA).¹⁰ By 1989, with the fall of the Berlin Wall and the decline in the global threat of

nuclear warfare, FEMA was funded and empowered to focus its efforts on non-nuclear disaster response as well. The current basis for federal disaster response stems from the Robert T. Stafford Disaster Relief and Emergency Assistance Act (most commonly known as the “Stafford Act”). This law gives the federal government operational guidelines and funding to execute disaster response.¹¹

CURRENT PRACTICE

This section describes many local, state, and federal assets or policies that can be used when an organization sets out to develop a mutual aid plan. The activity level and effectiveness of organizations and policies vary, and although each possibility described in this section may not have all the answers, each provides a place to start and is part of the overall context of mutual aid.

Local Community Assets

All disasters begin as local events. Community-level first responders typically serve on the front lines for disaster response, often placing their own personal safety in jeopardy in the process. Some disasters, such as biological terrorist events, may develop slowly over time and great distances, yet the first case is often identified by a local healthcare worker or rescuer who notes an unusual incident, such as the physician who diagnosed the incident case of anthrax in 2001.¹²

Disaster or emergency planning in communities has historically been developed by fire departments, in part as a result of their personnel’s ongoing training and experience in managing day-to-day emergencies. Town managers or mayors have overall responsibility; however, fire departments have typically served as both planner and operator. Law enforcement agencies also play a major role in developing the overall response plan. Close integration of these two departments remains critical to the successful planning and execution of emergency and disaster response plans, the goal of which is public safety for the community’s residents. These departments develop mutual aid relationships with other towns or localities to provide support for events that exceed their departments’ capabilities. Other agencies have been less involved in such preparation.

Local Emergency Planning Committees

Although since 1986, communities, by law, have had to develop a Local Emergency Planning Committee (LEPC), the events of Sept. 11, 2001, dramatically increased the emphasis placed on these organizations to expand their disaster planning process. Planning now must occur not only across some jurisdictional boundaries, but it also must entail other entities beyond industry, fire, and law-enforcement personnel. Specifically, the federal government in 1986 mandated the formation of State Emergency Response Commissions (SERCs); these SERCs were tasked to develop emergency planning districts to “. . . facilitate preparation and implementation of emergency plans.”¹³ Within these districts, the state is to “. . . appoint members

of a local emergency planning committee for each emergency planning district. Each committee shall include, at a minimum, representatives from each of the following groups or organizations: elected State and local officials; law enforcement, civil defense, firefighting, first aid, health, local environmental, hospital, and transportation personnel; broadcast and print media; community groups; and owners and operators of facilities subject to the requirements of this subchapter.”¹³ In areas where an LEPC is active, it can serve as the focal point in the community for information and discussions regarding all aspects of emergency planning as well as health and environmental risks.

US Citizen Corps

The federal government created the USA Freedom Corps after Sept. 11, 2001, in an effort to provide opportunities for citizens to serve their community and foster a culture of service, citizenship, and responsibility. Although federally managed, components of the US Citizens Corps, an arm of USA Freedom Corps, are designed to be staffed by local volunteers and serve in local events. The Community Emergency Response Team (CERT) program helps train individual volunteers to be better prepared to assist their community, serving as support to first responders, directly assisting victims, and organizing volunteers who arrive on-scene. They also can assist in projects designed to enhance public safety.¹⁴

The other major component of the US Citizen Corps available for assistance at the local level is healthcare personnel who serve as part of the Medical Reserve Corps (MRC). “The MRC program coordinates the skills of practicing and retired physicians, nurses and other health professionals as well as other citizens interested in health issues, who are eager to volunteer to address their community’s ongoing public health needs and to help their community during large-scale emergency situations.”¹⁵ The Office of the Surgeon General within the U.S. Department of Health and Human Services oversees the program, but its components, tasks, activation, utilization, etc. are governed locally and through state Citizen Corps Councils. Local community leaders develop MRCs and outline their roles and responsibilities in disaster response. MRCs may also play a role in day-to-day public health and safety campaigns or other volunteer efforts. Finally, they may cooperate with the local Metropolitan Medical Response System (MMRS) and assist with local disaster medical assistance teams.

Metropolitan Medical Response System

Many areas around the country now have MMRS projects. This national program started in 1996 under the U.S. Department of Health and Human Services, but it has shifted to the Department of Homeland Security under FEMA’s oversight. Each MMRS contract is awarded to a region that agrees to complete a series of steps toward regionalizing its medical response capacity and preparedness. The main thrust of the program is to develop robust regional systems that coordinate existing plans and resources and assist agencies in planning, training, and exercising together. Initially developed to regionalize

response around major cities, MMRS projects now exist in broader regions. The most recent MMRS project, started in 2003, covers three northern New England states. (More information is available at: <http://www.nnemrs.org>.)

Like the LEPCs, MMRS projects have a mandate to include people from a wide variety of disciplines in a coordinated planning effort. As a result, they make an excellent starting point for finding pre-existing knowledge of resources and cooperative agreements that helps make new mutual aid agreements strong.

Other Government Agencies

A variety of other government organizations may play a prominent role in local disaster response. Search and rescue organizations may come from state Fish and Game agencies, private organizations, Civil Air Patrol, and others, although federal agencies, local military, Veterans Affairs, federal law enforcement agencies, etc. may serve as first responders for some communities and hence need to clearly predetermine their roles, responsibilities, and command relationships during disaster planning.

Voluntary Organizations and Volunteers

The American Red Cross (ARC) plays an active role in the health and safety in most communities, and although it is not a government entity, it has a federal mandate to assist in disasters.¹⁶ It is a lead primary agency for Emergency Support Function #6 (Mass Care) in the National Response Plan. Staffed by both professionals and volunteers, ARC's disaster relief is designed to meet the immediate, disaster-related needs of victims as well as emergency workers. It provides shelter, food, and health and mental health services to address basic human needs during the event and later provides services to help disaster victims and emergency workers return to some form of normalcy. Its special shelters could also be called on to assist in the care and management of hospitalized patients who are discharged because of low acuity or evacuated because of disruption of the hospital facility. The ARC normally provides care to all victims who arrive at one of its shelter for support, but pre-event mutual aid agreements and discussions can help coordinate disaster health services within a given community.¹⁷

Other relief agencies appear at disasters and play a role in supporting both victims and rescue workers. At the Pentagon disaster on Sept. 11, 2001, the first agency to arrive was the Salvation Army (J. Geiling, personal observation). The Salvation Army is a Christian-based international organization whose mission includes "... To provide support, training and resources to respond to the needs of those affected by emergencies without discrimination."¹⁸ Additional religious or other cause-related organizations serve, in part, to assist their community in times of need.

Individual volunteers also tend to flock to disaster scenes, in part to assist with the rescue effort. This "convergent volunteerism" can be defined as "... The arrival of unexpected or uninvited personnel wishing to render aid at the scene of a large-scale emergency incident [and

who often] engage in freelancing, [that is,] operating at an emergency incident without knowledge of or direction by the on-scene command authority."¹⁹ These volunteers are not limited to medical personnel, but also can include fire and law enforcement representatives and others. They migrate to the scene, in part as a result of misinformed requests for help often by well-intended media reporters, politicians, or professionals from their specific organizations.

Challenges facing these volunteers and those tasked to oversee the response effort include volunteer safety; interference with the operations; security, especially at a crime scene; and qualifications as responders. These "credentials" may be typical medical skills and licensures of healthcare providers who arrive on-scene, but they apply to others who appear as well. For example, incident managers often need to deal with firefighters who self-dispatch to a scene—they may be helpful with their specific skill sets but are unproven, unknown, and may pose safety hazards on-scene. Hence, some have posed the establishment of a national system of fire service credentialing.²⁰ Finally, for large-scale disasters, sustained operations will require the expertise of professionals working later shifts in their normal place of employment; organizations' effectiveness will be depleted if their personnel report to the disaster scene as unsolicited volunteers.¹⁹

Volunteers will likely continue to converge on disasters because of two reasons: (1) volunteers, especially first responders, are genuinely altruistic and want to help, and (2) they often are unsure as to the exact need, so assuming any help is better than none, they migrate to the scene. People who are used to going to disasters will likely continue in their quest to provide aid. However, rapidly obtaining a needs assessment and disseminating such information may prevent unnecessary aid; this communication depends on a functioning, well-tested, interorganizational mutual aid two-way radio system. Key responders to area disasters should proactively determine such roles and responsibilities, especially in scenarios that typically involve multiple organizations or jurisdictions.

Convergence behavior is often not limited to the movement of personnel. Unnecessary donations of equipment, clothing, and medical supplies (including blood products that require significant logistical and administrative support) can also appear at a disaster scene. Managing this collection can, unfortunately, use critical assets needed to manage the disaster itself.²¹

Local Emergency Management Plans and Mutual Aid

A review of the agencies and personnel available as well as thought given to who else may show up at a disaster are important aspects of the planning or mitigation phases of disaster response. Formalizing this information into a plan and developing mutual aid agreements optimize the chances for successful disaster relief operations. Developing a plan at the local level can be a daunting job for the individual(s) tasked (or who volunteer) to complete it. The National Response Plan outlines the basic components for a plan, but often state governments provide their towns with a template. For

example, the state of Vermont's "Model Town Emergency Operations Plan" guides communities through purpose statements, hazard vulnerability analysis, operations, support resources, exercise and training, and other components needed to complete a town plan. Details on specific emergency support functions can be found in its 13 annexes.²²

Other locations, typically large cities, may present more complicated situations—multiple agencies from a variety of jurisdictions and levels of government not only interact for daily operations, but also for emergencies and disasters. The metropolitan Washington, D.C., area has established a 17-member Council of Governments (COG) to help in a coordination effort for the region. Collectively, with input from the state of Maryland, the Commonwealth of Virginia, the federal government, public agencies, the private sector, volunteer organizations, and local schools and universities, the COG has established a Regional Emergency Coordination Plan (RECP) to provide a vehicle for collaboration in planning, communication, information sharing, and coordination activities before, during, or after a regional emergency.²³ The plan describes the purpose and scope, as well as the roles, responsibilities, communication, and coordination relationships among member organizations. In a manner similar to the Vermont plan, the RECP delineates its emergency support functions into 15 areas, or regional emergency support functions (R-ESFs), which "identify organizations with resources and capabilities that align with a particular type of assistance or requirement frequently needed in a large-scale emergency or disaster."²³ The 15 R-ESFs are transportation; communications infrastructure; public works and engineering; firefighting; information and planning; mass care; resource support; health, mental health, and medical services; urban search and rescue; hazardous materials; food; energy; law enforcement; media relations and community outreach; and donations and volunteer management.

These regulatory structures and component organizations all desire to serve the public in time of need. However, the political, economic, and structural viability of each one and its individual members depends to a large extent on prearranged relationships and mutual aid agreements that are designed to provide emergency assistance to each other in the event of an emergency or disaster. The conditions of these arrangements may be to provide reciprocal services or to receive direct financial reimbursement for labor, supplies, or equipment. Ideally the arrangements are codified in writing before an event, although they may be based on unwritten mutual understanding and may even occur after an event has taken place. FEMA's Mutual Aid Agreements for Public Assistance (Recovery Division Policy Number 9523.6) specifies criteria by which FEMA recognizes the eligibility for reimbursement of costs under the Public Assistance Program incurred by such mutual aid agreements.²⁴

Well-developed mutual aid arrangements, particularly in major metropolitan areas, such as that previously outlined for the Washington, D.C. area, make reimbursement for services more likely. For example, the Washington, D.C. area COG received recognition and congressional support

in December 2004 for its National Capital Region Mutual Aid Act, which it then adopted in April 2005.²⁵

First responders outside of regions with developed mutual aid agreements, such as in very remote areas, must also consider how they will share their resources. Often their assets are very limited in scope and are charged to cover large areas. Funding for such enterprise has been limited in the past. However, the federal government's 2003 budget earmarked \$140 million to assist rural communities with planning and establishing mutual aid agreements.²⁶

Finally, even though well-defined, codified mutual aid agreements serve all parties who participate in disaster response, it is the *process* by which disaster planning and mutual aid arrangements develop that is most crucial to a successful disaster response. It is through the planning process that relationships among emergency response organizations, both inside and outside of the planners' jurisdiction, develop. Exchanging business cards, rehearsing plans through exercise drills, refining communications plans, and other activities during disaster preparedness all foster a sense of trust among the participating organizations, thereby improving overall interorganizational and intraorganizational communications in a disaster.²⁷

Hospitals

Hospital disaster preparation and incident planning have had a dramatic surge in importance since Sept. 11, 2001. Legislation delegating hospitals as first responders also makes them eligible for funding to support the planning process, an often-quoted impediment to their preparation.²⁸ Individual hospital preparation and response to an incident have been reviewed in detail elsewhere.²⁹ However, outside organizations and agencies continue to expand their expectations for hospitals to be adequately prepared. Unfortunately, though, hospitals often tend to conduct their disaster preparations and training in isolation, which impairs their ability to interact with these groups when disaster strikes.

As previously outlined, LEPC guidelines recommend that local hospitals participate in the community's emergency preparation. In addition to routine agreements on patient receiving and treatment, these preparations now call for expensive and underfunded capabilities such as planning for the reception of contaminated chemical casualties. Hospitals' primary credentialing oversight comes from the Joint Commission on Accreditation of Healthcare Organizations (JCAHO). This body also mandates a variety of emergency preparations that, again, require additional expensive preparations. If hospitals do not receive adequate financial support and therefore are not prepared, victims of mass casualty incidents may end up riding "ambulances to nowhere."³⁰

JCAHO, however, continues to refine its requirements. The bulk of JCAHO's requirements for emergency preparedness lie in its Environment of Care (EC) section. Elements of performance for EC 4.10 require hospitals to establish with the community a hazard vulnerability analysis, the hospital's role relative to the community's emergency management plan, and an "all-hazards" command structure that easily melds with the community's

command structure. Exercises that test the plan must be conducted twice each year, one of which must include participation in a community-wide exercise (EC 4.20).³¹

Hospitals affected by disasters often become inundated with victims seeking care, who in reality need minimal medical attention. Additionally, individuals who may simply need observation during the latency period of a potential biological hazard may overwhelm a hospital's requirements to treat the more seriously ill or injured. To prevent this increased burden, hospitals should explore mutual aid agreements with special shelters, such as those managed by the ARC or other volunteer organizations, as previously discussed. Additionally, urgent care centers, individual physician or healthcare worker clinics, mental health clinics, surgicenters, nursing homes, etc. may all be additional locations to provide care for low-acuity cases. These facilities and others may also help individuals seeking care who really only need shelter. In combination, hospitals may be able to work with these organizations to accommodate much-needed surge capacity, a topic covered in detail elsewhere in this textbook.

There are other models that communities can use to develop scalable triage, treatment, and dispensing facilities external to normal care centers. One such example, developed by a team of military and civilian specialists, is the *Modular Emergency Medical System*.^{32,33} Along with general planning guidance for mass casualty incidents, this series of publications includes detailed plans for two types of centers that can be quickly set up to help relieve the burden on hospitals. The Neighborhood Emergency Help Center concept is designed to manage asymptomatic and noncritical patients, providing limited care and treatment.³⁴ The Acute Care Center (ACC) concept provides a means of caring for those who need inpatient treatment but do not require advanced life support or intensive care.³⁵ These models can be tailored to area needs and resources and provide a realistic way for communities to manage mass care incidents. In fact, the ACC concept is recommended in the current Health Resources and Services Administration (HRSA) grant guidance.³⁶ Finally, the U.S. Department of Health and Human Services is developing a series of Federal Medical Contingency Stations to use to support surge capability needs of local healthcare facilities.³⁷ Each of these center concepts was designed to encourage communities to make use of existing facilities to house the centers and requires advance effort to develop memoranda of understanding with facility owners and mutual aid agreements to ensure that the center can be set up, staffed, and demobilized without depleting hospital resources.

Volunteers present a significant challenge to those planning for and managing a response. As previously discussed, well-intending volunteers tend to converge at a disaster to provide their assistance. This sense of duty also applies to healthcare providers who arrive at an overwhelmed or damaged hospital to assist in needed patient care activities. During disaster planning, the facility needs to decide whether volunteers will be used or in what roles they will be used; if nurse or physician volunteers will be used; and if so, how will the credentials of volunteers be verified.³⁸ The American College of Emergency Physicians recommends that all hospitals

have a detailed process in place to allow for the emergency privileging of additional physician staff who arrive at a facility to support response efforts to a declared hospital disaster. So-called "disaster credentialing" should ideally be completed before an event and mirror the credentials of the providers at their "home hospitals." In the event of a disaster, immediate credentials can then be granted with proper identification. Hospitals providing these disaster credentials must also be prepared to provide professional liability coverage for physicians who provide care during a disaster in their institution and be prepared to address issues of compensation for injured workers.^{39,40} The provision of disaster credentials must follow the medical staff guidelines outlined by JCAHO under Medical Staff (MS) 4.220. The elements of performance for this standard include identifying the individual(s) responsible for granting such privileges, a mechanism to manage those with these credentials, and the development of a priority pathway to verify credentials as soon as practical after an event.³¹

Identification and credentialing are topics that can be included in mutual aid agreements to the benefit of the entire community or state. As responders and volunteers appear on-scene, it is critical that security personnel are able to determine who is allowed to work and in what capacities, often without the benefit of a sophisticated understanding of licensure and credentialing. Coordinated standards for identification can increase the speed and accuracy of this process. Some national initiatives are under way, such as the fire service credentialing proposal previously described. Another initiative is HRSA's funding for the Emergency System for the Advance Registration of Volunteer Health Professionals (ESAR-VHP) program, which is an attempt to provide standardized credentialing and identification protocols. (The basis for the ESAR-VHP initiative is U.S. Public Law 107-188, the Public Health Security and Bioterrorism Preparedness and Response Act of 2002 [section 107, Emergency system for advance registration of health professions volunteers]). (PL 107-188 is available at: <http://thomas.loc.gov/>.) The 2005 HRSA guidelines require awardees to develop ESAR-VHP activities in their regions. The most recent ESAR-VHP guidelines were released in June 2005. However, healthcare facilities should seek out local initiatives and actively participate to ensure that their needs are addressed and that they are aware of the systems that are developed in their communities.

Like other community-based organizations, hospitals must share resources and plans with other entities in the community. Mutual aid agreements or memoranda of understanding formalize and delineate each other's roles and responsibilities. Agreements need to include not only representatives from public safety and community industry, but also those from other nearby healthcare facilities. Developing a detailed, yet functional, mutual aid agreement between medical facilities can be a challenging task. Much coordination, inspection, discussion, legal review, etc. must occur before most signatories will agree to such arrangements.

Fortunately, several templates exist to aid the process.⁴¹⁻⁴⁴ These models include information such as

the purpose of the memorandum of understanding, timing and method of communicating requests, documentation standards, guidance on patient transport, hospital supervision, financial and legal liabilities, and notification of next of kin and the patient's physician. It is also important that these topics be discussed not only in general principles of medical operations, but also as they apply to the evacuation of patients and the transfer of personnel, pharmaceuticals, supplies, or equipment.

Command Structure

When disaster strikes a community, local, community-level assets typically respond first. The majority of organizations in the first responder community attempt to establish command and control of the scene using principles of the Incident Command System (ICS). Discussed in detail elsewhere in this textbook, ICS establishes a proven organizational template that can be expanded or contracted in a modular fashion to meet the demands of the event. The emergency medical services (EMS) branch of the operations section is supposed to manage medical support to the operation. Under the National Incident Management System (NIMS), which is discussed in detail elsewhere in this textbook, a medical unit is also established under the logistics section to provide medical support to the emergency responders themselves.⁷ If the incident is primarily a mass casualty event involving essentially all medical assets, then the operations section chief, or even the incident commander, may be from the health sector.⁴⁵

This organizational paradigm is often not followed by hospitals in their response to either an internal or external disaster; they tend to rely on their own organizational structure that has evolved to support their day-to-day operations. However, when disaster strikes, hospitals need to move toward an emergency management structure to ensure institutional and personnel safety and security, optimize patient care, and efficiently use scarce resources. As previously mentioned, JCAHO mandates an emergency management system that easily integrates into that of the community.

The Hospital Emergency Incident Command System (HEICS) is fast becoming the standard for healthcare systems' disaster response. The organization of HEICS mirrors that of ICS, with five functional areas: command, operations, planning, logistics, and finance and administration. Job action sheets provide checklist tools for providers in each position to prioritize and categorize their efforts into immediate, intermediate, and extended tasks. HEICS is not a turnkey system; rather it is a process that must be adapted to each event and is supported by specific emergency management policies and procedures.⁴⁶ The HEICS structure focuses on management of internal disasters. As previously discussed, coordination with external agencies becomes necessary for the facility to effectively integrate itself into any community disaster response. HEICS can begin to facilitate that process by ensuring that outside groups and leaders that follow ICS principles can (ideally) find their hospital-based counterpart in the ICS structure to better coordinate the disaster response.

State and federal assets that arrive on-scene will similarly fall in line with their own form of an ICS; any interorganizational variations will likely change to adhere to new guidelines published in NIMS.⁷ A major event may result in the establishment of multiple incident command posts (ICPs) and agency Emergency Operations Centers (EOCs). To manage the entire event, representative agencies may meet to form a Joint Operations Center (JOC), usually off-site to effectively provide a strategic, unified command (J. Geiling, personal observation).

Healthcare workers often believe that daily emergency care and practice suffice in the translation to disaster preparedness. Although medical and administrative skills normally work in common emergencies, they do not adequately prepare the individual healthcare worker or institution for the chaos of a disaster. For example, disasters often require the completion of tasks that do not normally occur in routine emergencies, such as scene security, search and rescue operations, patient movement and evacuation activities, media operations, and overwhelming requests for information. Failure to understand the organizational milieu of a disaster setting risks putting various types of providers into settings where independently they seek to do good but collectively they endanger themselves, their patients, and the scarce resources on hand.⁴⁷ Hence, an understanding of disaster organization becomes imperative for a safe and effective individual and organizational response. This understanding is also essential for the effective requesting and management of mutual aid assets.

State Assets

As previously discussed, most disasters begin as local events and are managed with local, community-level assets. State and federal agencies located in the vicinity may also serve as first responders without full escalation of the response outside of the community. When community resources become overwhelmed or other characteristics of the disaster mandate state or federal involvement (such as in multijurisdictional fire response or events related to terrorism), individual state emergency management organizations respond.

National Guard

Many state assets can be called on to support a state-managed disaster response. Integrating them into the state emergency management plan naturally requires detailed planning. One organization that is often overlooked, in part because of its perceived complexity, is the National Guard. At the disposal of the governor, National Guard units serve the public interest in their state in time of disaster, unless they are called on for federal service. Recently, the National Guard Bureau formed new units, called Civil Support Teams, Weapons of Mass Destruction (CST (WMD)). These teams, under the operational control of the adjutant general and ultimately the governor of each state, are designed to mobilize within 2 hours to augment local and regional terrorism response, principally for events known or suspected to involve weapons

of mass destruction, including nuclear, chemical, or biological agents. When deployed to an event, these teams report to the incident commander and provide assessment capabilities, advice, and assistance to the response effort. In essence, they supplement other fire and hazardous materials teams that may be on location, serving as a bridge until other state or federal assets arrive.⁴⁸

State Emergency Response Commission

Each state develops its own disaster organizational system. However, the same legislation that mandated the establishment of LEPCs previously described, also directed the establishment of SERCs.¹³ Appointed by each governor, "... SERCs [normally] have been formed from existing organizations such as state environmental, emergency management, transportation, or public health agencies. In others, they are new organizations with representatives from public agencies and departments, along with private groups and associations."⁴⁹ SERC duties include the establishment of local emergency planning districts and LEPCs within each district, coordination and supervision of LEPC activities, oversight of proposals for and distribution of training funds, and annually reviewing local emergency plans.

Emergency Management Assistance Compact

Disasters that cross state boundaries may be managed at the state level, without necessarily invoking the need for a federal response, under the auspices of the Emergency Management Assistance Compact (EMAC). Legislated in 1996 as Public Law 104-321, EMAC is a mutual aid agreement and partnership between states that exists because of the common threat from a variety of disasters; it is a legal mechanism and not an organization. Out-of-state aid organized through EMAC helps ease the movement of personnel and equipment across state borders. Requests for EMAC assistance are legally binding contracts, obligating the requesting state to reimburse all out-of-state costs and liability complaints for out-of-state personnel. Finally, EMAC permits states to both ask for assistance and to provide available resources with a minimal amount of "bureaucratic wrangling."⁵⁰

Model Intrastate Mutual Aid Legislation

Produced by the National Emergency Management Association, in concert with the Department of Homeland Security, FEMA, and other emergency responders, the Model Intrastate Mutual Aid Legislation provides a robust template to expand on the mutual aid agreement legislated under EMAC. A multidisciplinary group of subject matter experts gathered in January 2004 to review a variety of mutual aid agreements, from all levels of government, and on thorough review and evaluation of "best practices" developed this template. Covering 11 basic articles, "... The model is meant to be a tool and resource for states and jurisdictions to utilize in developing or refining statewide mutual aid agreements. It is anticipated that states and jurisdictions may wish to modify the model to conform to their own state

laws and authorities, or to address unique needs and circumstances. Further, the proposed articles and provisions in the model are complementary to the recommended minimum elements to be included in mutual aid agreements that are a part of the draft National Incident Management System Plan."⁵¹

Federal Assets

Once a the disaster response exceeds the capabilities of local, state, or inter-state capabilities or the disaster results from a recognized act of terrorism, federal resources mobilize to assist the community. A large number of diverse organizations with many differing capabilities can be called on to assist; many of these are discussed in detail elsewhere in this textbook. In larger metropolitan areas, but also in local areas adjacent to federal facilities, these assets may appear immediately on-scene, serving in a first responder capacity. However, outside of this example, federal assets mobilize in a specified manner, according to federal policy.

The governing document for the federal response is the National Response Plan (NRP). As previously noted, this plan serves as the basis for tailoring the federal response to the needs of the disaster. Under the guidance of FEMA, now assigned to DHS, lead agencies and supporting agencies for the 15 Emergency Support Functions (ESFs) provide a robust response capability.⁶

The NRP has entirely replaced the Federal Response Plan. "National" is an intended change to the name of the plan, emphasizing the federal government's ability to tailor its response, across the spectrum of government, to assist local officials and agencies.⁵²

The Disaster Declaration Process and Federal Disaster Assistance

When disaster strikes, individual communities, states, and other organizations cooperating through mutual aid agreements respond to assist the afflicted area and its victims. As noted, some federal assets may be on hand, and depending on the scenario (for example, a terrorist event), others may preemptively deploy to the scene. Outside of these settings, the federal disaster declaration process to request federal assistance follows the guidelines outlined in the 1988 Robert T. Stafford Disaster Relief and Emergency Assistance Act. This Stafford Act requires that "all requests for declaration by the President that a major disaster exists shall be made by the Governor of the affected State."⁵³

The governor's request is processed through the regional FEMA office. The first step is a preliminary damage assessment (PDA) conducted by state and federal officials. This assessment, in concert with the governor's request, must demonstrate a need beyond the capabilities of the local and state governments. The PDA normally precedes the governor's request, though it may follow for obviously catastrophic events. Pending the approval of federal assets, the governor must initiate the state's emergency plan, documenting the resources used for the state's response. Also required is an impact estimate, which is a projection of the financial cost to the

public and private sectors. Finally, the governor must provide a needs assessment on the assistance required. Based on this information and with the governor's appeal, the president decides on the validity of the request; declaration of the event as a federal disaster activates a broad scope of federal programs and services to assist in the response, rescue, and recovery operations.⁵³

National Mutual Aid and Resource Management Initiative

As higher levels of government respond, the greater the capabilities, but also the complexities of the response. Pre-established mutual aid agreements and packages of response capability may enhance the timeliness of the entire response effort. An effort to streamline the process of developing mutual aid agreements and managing resources, the National Mutual Aid and Resource Management Initiative, is being spearheaded by FEMA in concert with the National Emergency Management Association. Through this initiative, FEMA hopes to provide for an efficient and effective all-hazards disaster response.

Once implemented, the system should enhance readiness and response, at all governmental levels, by allowing emergency management personnel to identify, locate, request, order, and track outside resources quickly. Key concepts of this program include use of preincident mutual aid agreements; protocols for the documentation and inventory of disaster response resources; a national deployable inventory of preidentified, credentialed, categorized, and capability-typed resources; and an automated resource management system to track all disaster resource requests.⁵⁴ Finally, to help ease the burden on emergency managers in deciding the resources required for the disaster, this initiative seeks to type, or group, federal, state, and local assets into eight disciplines. These groupings will help ensure that the needed support capability reaches the requestor at the disaster.

OPERATIONAL PITFALLS

This section describes two of the most common pitfalls that can undermine even the best mutual aid plan or response operation.

Two-Hat Syndrome

Although the organizational construct for disaster response introduced here, and detailed elsewhere in this textbook, is designed to ensure a thorough, robust, and responsive disaster response capability, vulnerabilities jeopardize response effectiveness. Many weaknesses have been described and experienced by emergency management personnel. However, no disaster response can be affected without experienced, healthy, and available responders.

As government budgets become strained with daily needs and now the additional demands of homeland security, available personnel assets become less available. To help continue with necessary services, many agencies

require individuals to perform a “dual-hat” mission, carrying the burden of two positions. People, who are asked, required, or who volunteer for such duties may jeopardize response efforts in the event of a disaster. This “two-hat syndrome” also often extends beyond the public sector. For example, asking part-time or off-duty persons to assist in relief efforts means they may not be available for other needed services that they normally perform. Agencies that have mutual aid arrangements may, in fact, be sharing personnel. These challenges are magnified during military activation of Guard or Reserve forces—many of these personnel also work in other public sector jobs. Surveys have determined that of all of the public service sectors, fire and rescue operations, private ambulances, and emergency management services suffer the most from this “syndrome.”⁵⁵ Clearly this issue complicates disaster response and necessitates consideration during predisaster planning and training.

Complicated Wire Diagram—Who's in Charge?

Finally, the detailed emergency response capabilities described in this textbook all may eventually meet “on the battlefield” at the disaster scene. Defined command and control relationships, policy guidelines, regulatory edicts, mutual aid agreements, memoranda of understanding, or simple “gentlemen's agreements” outline the ideal mechanism for all parties to execute a disaster response. However, when disasters occur, the agencies that arrive to assist often come from different locations with differing and, oftentimes, competing ideas on management of the disaster. Mutual aid and working arrangements, even if prearranged rather than being developed on scene, often have not been rehearsed. Consequently, individuals who respond to a disaster need to have both the flexibility and the authority granted by their parent organizations to improvise on-scene. This “planned improvisation” should be both expected and, ideally, rehearsed during disaster planning.⁵⁶

Additionally, the decision makers who arrive on-scene tend to come from lower levels in their organizations' hierarchy. They often fail to understand their organization's participatory role in the overall disaster response, focusing instead on their more familiar intraorganizational policies and procedures. In disaster parlance this is known as the “Robinson Crusoe Syndrome” (i.e. ‘we're the only ones on the island’). This narrow focus on one's organizational goals has been observed not only in disaster response, but in planning as well.⁵⁷ This dilemma also highlights the importance of training that focuses on interagency or interorganizational response, which unfortunately does not occur very often.

SUMMARY

Mutual aid arrangements among agencies likely to operate in a disaster clearly enhance the probability of success, giving robust and redundant response capabilities. The key to the success of the effort lies in the people—their availability, physical stamina, understanding of the disaster

response milieu, and pre-event training. Only through rehearsal will the nuances of these arrangements and capabilities be delineated and repaired to meet the needs of the victims who depend on the responders and their plan.

Surge Capacity

Julie Ann P. Casani and Albert J. Romanosky

The events of 2001 are often cited as being pivotal for a new definition of preparedness. In actuality, there were multiple factors forcing the healthcare industry to look at surge capacity before the 2001 terrorist attacks on the United States. Beginning more than two decades earlier, crises in emergency department overcrowding provided insight into the necessity for flexing the number of hospital beds, providing rapid discharge of inpatients, delaying scheduled surgeries, diverting ambulances based on triage criteria, and altering practice paradigms to allow “auxiliary” nursing staff to provide necessary emergency care. Since 2001, events such as severe acute respiratory syndrome (SARS) and smallpox preparedness have illustrated the need for surge capacity and the ability of facilities not only to flex upward the number of beds but also to supply specialized or specified treatment (e.g., high-level respiratory isolation). The majority of surge planning has focused on trauma care for victims of multicasualty incidents; terrorist and industrial chemical incidents; and public health emergencies, such as bioterrorism and natural epidemics. There are discrete differences in the type of capacity needed for each type of incident, but there are overarching principles that can benefit surge capacity planning for all-hazards disaster planning.

One of the great challenges has been funding for surge capacity. Health economics in the United States, in an attempt to limit escalating healthcare costs, has resulted in the overall reduction of acute care inpatient beds and has eventually led to a vastly expanded network of industry related to home care and intermediate care facilities. In most acute care hospitals, making the “bottom line” is a challenge in itself, let alone providing services and capacity for an event that may never happen, developing resources that are costly with limited or no pre-event funding, and planning for expenditure of resources that may not be reimbursed. The end result is opposing forces and policies in which preparedness efforts are attempting to increase surge capacity while cost containment measures are shifting care away from acute care centers (ACCs).

Surge capacity has been defined as encompassing “potential patient beds; available space in which patients may be triaged, managed, vaccinated, decontaminated, or simply located; available personnel of all types; necessary

medications, supplies and equipment; and even the legal capacity to deliver health care under situations which exceed authorized capacity.”¹ Integral to this definition are the multiple elements, not solely facilities or beds. Hick and colleagues² go on to define surge capability as the “ability of the health care system to manage patients who require specialized evaluation or interventions.” This distinction is important because it focuses on the more specialized resources and nonfixed bed capabilities. Historical events and theoretical models provide estimates of the number of acutely ill people requiring care after disasters. However, the definition of an “acutely ill or injured” patient is case-dependent and does not reflect the *level of care* the victim may require. Trauma-related projections range from 100 to 300 patients/1 million population after mass casualty incidents (MCIs) to 300 to 600 patients/1 million population, according to the National Disaster Medical System (NDMS) plans. There are limited projections for bioterrorism or large-scale communicable disease models. These include the NBC-CREST (Department of Defense) model estimates of 500 patients/1 million population and pandemic influenza planning estimates of 15% to 35% of the population. The pandemic influenza model assumes a gross attack rate of 30% and would result in five times as many influenza-related hospitalizations and deaths as in a regular influenza epidemic with the current levels of vaccination in the population, mostly in persons ages 65 and older.³ Based on data from the influenza pandemic of 1918 to 1920, projections were made with respect to the current population of Germany (approximately 82 million). An estimated 20 million to 25 million cases of influenza will occur, with 200,000 admissions to hospitals, resulting in a total of 1.6 million days of hospitalization, 120,000 deaths from influenza, and an annual excess mortality of 175,000. This is a ratio of 2500 hospital patients/1 million population. Approximately 1.2 million cases of pneumonia as a secondary infection also should be expected.⁴

Because of the wide spread of estimations, which are dependent on the causative agent, for planning purposes, many use 500 adult and pediatric victims/1 million population above the daily capacity to calculate surge capacity. A regional capacity requirement example is found in Table 28-1; Region A is an intrastate region in which City A is located.⁵

TABLE 28-1 REGIONAL CAPACITY REQUIREMENT

	POPULATION	SURGE (BEDS/PATIENTS)	CURRENT DAILY CAPACITY	INCREASE
State A	5,595,211	2798	10,006 (48 facilities)	28%
Region A	2,571,695	1286	6129 (22 facilities)	21%
City A	628,670	314	3827 (12 facilities)	8%

Most projection prototypes assume the current health-care delivery model, which may or may not be attainable or sustainable at high levels of patient load. Regardless of cause, to approach projected levels of surge demands, multidisciplinary, multientity, regional, collaborative planning must be undertaken because no single component can provide all of the necessary resources. The authors of the Agency for Healthcare Research and Quality document, *Regionalization of Bioterrorism Preparedness and Response*,⁶ conclude that “regionalization is likely to benefit elements of a bioterrorism response including the provision of surge capacity in essential response services such as triage, the provision of medical care, distribution and dispensing of prophylactic therapies, outbreak investigation, security management, and emergency management. . . . Coordination of these organizations may benefit from implementation of information management strategies and pre-event agreements that specify response roles, remuneration, and chain of command.”

Overall coordination of planning and response is critical for implementation. The introduction of new modalities and paradigms presents a challenge to responders and the public who will instinctively react as they have in the past. If new programs and responses are expected to be implemented, then adequate communication, education, and exercises will reinforce this implementation. Incident management systems and Incident Command Systems must be integrated along with communications systems and protocols.

Multiple models have been postulated for the systematic, graded response necessary to provide a capacity to care for an overwhelming influx of patients.^{7,8} These models provide tool kits for evaluating the utilization of current resources and defining supplementary resources to provide the necessary location, staff, and supplies for response. Additionally, the type of incident may require a shift in necessary assets and availability of these assets. For example, the immediate response required in a catastrophic explosion will require a different strategy than the sustained nature of a wide-scale communicable disease event. Few of these models allow for healthcare staff to be among the ill or injured. In the Toronto SARS experience, the incident rates among nurses who worked in emergency departments, intensive care units, and coronary care units ranged from 10.3% to 60.0%.⁹ In addition, non-ill providers who fail to report for duty may further affect response. The potential unreliability of

the assessment of available resources may be especially troublesome if the healthcare workforce is particularly vulnerable physically or psychologically, as in the SARS outbreaks of 2003 and the early outbreaks of Ebola hemorrhagic fever. Likewise, few of these models anticipate the loss or compromise of a healthcare facility or access to it if it is located in close proximity to the event.

There are a number of dynamics that must be considered to prepare overall for a surge of acutely ill or injured patients. On a daily basis, the healthcare system attempts to provide the necessary triage, treatment, and health maintenance at a level that is determined as “normal operations.” A tentative balance of supply and demand is struck, based on dynamic shifts within a health system that is typically already at capacity. The actions implemented are variably applied and do not address the root causes behind the immediate crisis of overload: the critical nursing shortage, health insurance inequities, national malpractice concerns, and health economic trends. In many cases, the immediate demand is met and the system returns to an ever-increasing new normal of stress.

During the day, week, month, or season, if a peak in the number of patients is observed, then local, facility-specific provisions adapt to this increased demand by implementing “emergency operations.” This may result in longer office hours, emergency department diversion, longer wait time for ambulances, early discharge protocols, etc. A 2001 American Hospital Association survey showed that 60% of all and 80% of urban hospitals described their emergency departments as “at” or “near” capacity, as did 90% of all Level 1 trauma centers with more than 300 beds.¹⁰ One in eight hospitals reported emergency department diversion 20% or more of the time. About 20% of the hospitals’ capacity can be freed up by discharging existing patients, canceling elective surgery, and calling in off-duty staff. This response is usually (1) area limited, (2) time limited, (3) difficult but manageable, and, (4) occasionally “routine.” Repeated or prolonged stress at this level results in either a short-term (weeks) decay or, optimally, long-term solutions, such as increased staff, re-engineered space, etc. Close examination of these solutions provides important insight into potential solutions to a larger-scale, longer-term surge capacity situation. The incremental costs of re-engineering space to provide flexible utilization is much more cost-effective and allowable under most regulatory systems than is a fixed building or permanent assignment of space. The process involved in changing operations, such as surgery scheduling and staff shift flexibility, provides insight into the impact of long-term disaster services. For example, Rambam Medical Center in Haifa, Israel, can increase the number of burn victims it can handle from 15 to 136 by altering staff allocations and re-engineering space.¹¹

Larger-scale events, longer-term events, or those requiring specified care will place unique demands on a system, regardless of emergency operations preparedness. It should not be assumed that 100 times as many patients require 100 times the amount of response. At some point, which will vary depending on resources, community, and type of event, a critical threshold will be met in which “emergency operations” no longer suf-

fice. At this point, “disaster operations” are implemented. Efforts such as (1) “aggressive diversion” of patients to triage and decontamination facilities, (2) implementation of treat and release/refer protocols, (3) transfer of nonacute admissions to long-term care facilities, and (4) institution of widespread home care plans may be put into operation (Fig. 28-1). “Aggressive diversion” of patients refers to the direction or redirection of ambulances and patients away from acute care facilities to locations that provide triage, decontamination, and/or treatment. This may be done by transportation away from facilities, public information campaigns instructing people *not* to go to hospitals but rather to seek care at off-site centers, etc. Treat and release protocols and referral protocols may be implemented to allow for expedient care and throughput in alternative facilities or by physician and nurse extenders. Each of these programs requires extensive planning, policy and statutory research, and public dialogue in preparation for implementation.

CURRENT PRACTICE

A matrix of planning capacities is offered (Table 28-2). It is recognized that this is only one approach to maneuvering through the very difficult process of assigning resources and anticipating needs. This matrix is prepopulated and is provided as a starting point for planners. It is fully expected that communities may add or delete components that reflect available resources and cultural acceptance of their uses. A discussion of the components follows.

Arenas of care have been delineated with the assumption that there will be a continuum of care and that patients may not attend every arena. The “prehospital” arena is care delivered between the scene of the incident and definitive care. The care may be provided by tradi-

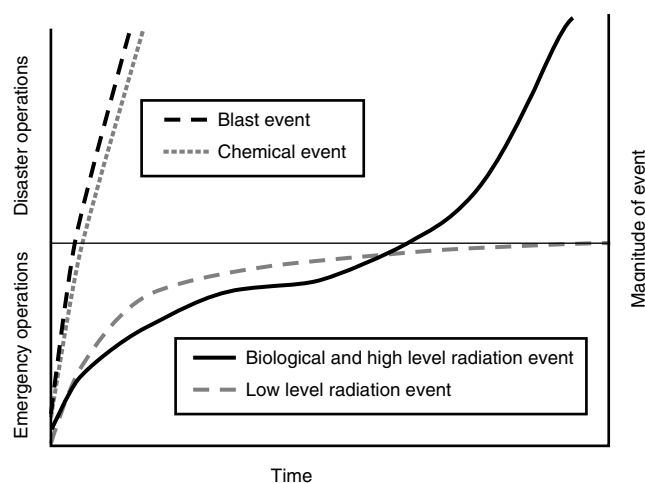

FIGURE 28-1. Response and magnitude of event plotted against time. Depending on the nature of the event, the healthcare system will attempt to respond to the increased demands. As demand for services increases, “normal operations” will be replaced by “emergency operations.” As the system is again stressed, the response shifts to “disaster operations.”

tional first responder entities (law enforcement, fire/rescue/emergency medical services [EMS], etc.) or via portable emergency triage and decontamination centers for large-scale events. This arena may also include any ad hoc informal community first aid centers. Integration of these may be a challenge, especially in light of limited communications and information systems. However, general public community education and preparation may eliminate a portion of the system’s surge demands. It may be assumed that not every person needs to be treated in a formal medical care unit. It may also be assumed that not every patient will be cared for in a pre-hospital arena and may self-refer directly to “traditional facilities.” In fact, the overwhelming majority of ambulatory patients are likely to self-refer to the nearest known traditional facility (hospital) in an acute disaster, such as natural disasters, explosions, etc. In some public health emergencies that develop and progress more slowly, this may or may not be the case. Education efforts and consistent, clear information programs and policies could affect this behavior.

“Traditional facilities” refers to locations where acute and general care is routinely delivered. These include emergency facilities, hospital- and nonhospital-based; private healthcare provider offices; small and large group practices; and community health centers, both private and those operated by public health entities.

During a health emergency, care may be shifted away from traditional facilities, either through naturally occurring forces or through policy and procedure implementation. It is commonly assumed that an expanded capacity within traditional facilities will provide the answer to surge demands. It is postulated here that if that were the case, then surge capacity would not be an issue at all other than building and supplying more traditional facilities. As elaborated earlier, this is antithetical to current market and overall health policy forces and is the very reason surge capacity becomes problematic. Therefore, to supply services during the increased stress of a health emergency, the system will need to look to “nontraditional facilities” in addition to the traditional facilities for resources. For a biological event or communicable disease public health emergency, this may include establishing treatment and triage centers not in hospitals but in other locations, such as long-term care facilities, hotels, and schools, perhaps using the Soldier Biological and Chemical Command (SBCCOM) Modular Emergency Medical System model.^{12,13} For a chemical event, this may be establishing locations for decontamination, triage, and treatment away from emergency departments, for example, in an off-site triage, treatment and transportation center (OST³C)¹⁴ if such a center can be established quickly and in close proximity to the event so that it is visible and accessible.

Finally, there can be many patients who are either not treated in an acute care facility of any kind but are referred home and are treated and/or followed-up at home or at a later time as referrals. This “nonfacility” domiciliary environment should not imply noncare. Instead this may require quite complex care and complex case management and will engage the medical and nonmedical communities and family resources.

TABLE 28-2 SURGE PLANNING MATRIX*

COMPONENT	PREHOSPITAL ARENA	TRADITIONAL FACILITIES ARENA	NONTRADITIONAL FACILITIES ARENA	DOMICILIARY CARE ARENA
Facilities	Triage facilities Decontamination facilities Private offices, community health centers, large group practices Transport vehicles (emergency medical service [EMS], private carriers, transportation sector resources)	Emergency departments, urgent care centers Hospitals Public health centers	Off-site treatment centers (acute care facilities) Long-term care facilities (off-site triage, treatment, and transportation center [OST ³ C])	Homes Dormitories Hotels

*This matrix is prepopulated with elements to begin planning efforts for surge capacity. Please refer to the chapter text for descriptions and discussion of the elements listed.

Facilities

Prehospital Arena

In areas where private-sector ambulances are not typically used for emergency transport, prior memoranda of understanding (MOUs) may be necessary to ensure availability, credentialing of personnel, emergency reimbursement, dispatch protocols, medical direction, etc. Additional resources from the transportation sector may be engaged, optimally with prior planning. Buses, taxis, and vans, both public and private service, can be used to transport large numbers of patients. Public-sector transportation vehicles are typically rapidly and easily accessible to government authorities. Many government authorities contract with private conveyance systems for more routine transportation needs. There may be opportunity to expand those contractual services to include emergency availability for transport not only of patients but, potentially, personnel. Finally, use of mass transportation vehicles may offer shelter for victims during the initial phases of a disaster.

Traditional Facilities Arena

Much has been done in the United States to prevent damage to critical structures from natural hazards such as earthquakes and floods. Seismic design provides

stability of hospitals and allows for maintenance of care in high-risk areas.

Traditional facilities typically provide surge capacity for beds by reallocating designated beds to the event. For example, postanesthesia areas that have cardiac monitoring capabilities may be turned into intensive care units. Hospital-based same-day surgical suites may be used in the treatment of acute injuries because they also house minor surgical supplies. Rooms with additional oxygen outlets that are used on a daily basis as a single-bed room can be used to cohort contagious patients.

As demand increases, patients requiring isolation who are dispersed throughout the hospital can be gathered into specialized multiroom units. Specialized needs for high-level respiratory and isolation units may be “created” by relatively low-cost engineering with the installation of ventilation deflectors that allow for negative air flow to those rooms individually or to a unit. In an incident, air flow and air exchanges can be adapted to provide flexible utilization of nonspecialty bed capacity. The authors of *Regionalization of Bioterrorism Preparedness and Response*,⁶ through retrospective analysis, determined that “pre-event hospital designation contributes to lower costs and improved patient outcomes. The evidence from trauma care regionalization suggests that a key component of high-quality, cost-effective care is limiting high-cost specialty care to specifically designated hospitals

with increased experience in treating severely injured patients. A bioterrorism response system may benefit from the pre-event designation of hospitals.” However, in the SARS events in Toronto, it was found that the transfer of patients to designated facilities may have contributed to further spread of the disease, especially early in the outbreak when control measures were still being clarified and made universal.^{15,16} Well documented in the literature and further described by Einav and colleagues¹⁷ in a study of terrorist-related MCI blast incidents, the most urgent and nonurgent victims are taken to the nearest hospital, even if it is not a designated trauma center. The authors suggest a paradigm shift in trauma care in which all hospitals should have some minimal level of capability for trauma care. In fact, the most recent model in Israel designates the nearest hospital as the evacuation hospital to which all trauma victims are taken. Only the most seriously wounded get surgical intervention while other less critical victims are sent to surrounding facilities after stabilization of life-threatening injuries, thereby making the facility serve as a triage center. In a mass-casualty event, referral and transfer to tertiary care facilities for advanced specialty care may be necessary and desired; however, in the disaster operation phase, these specialized services may no longer be available, either because the services have been diverted to general care or the specialty services are overwhelmed. Additionally, until or even after aggressive diversion of patients to triage centers is well established, patients may still self-refer to the hospital of their choosing for a number of reasons, including proximity, insurance coverage, and personal preference. It may be unpredictable as to which facilities will become a focus for care and likely that many, if not all, hospitals will become primary institutions. For this reason, *every* facility must be prepared to care for patients.

In addition to hospitals, other traditional facilities will be used through self-referral or through a planned, graded diversion triage plan. Patients with minor illness and injuries can be triaged to urgent care centers, public health centers, and community health centers. The results of a pre-event inventory of laboratory and radiologic capabilities will determine optimal triage protocols.

In disasters in which access to critical routine healthcare is disrupted, such as for patients undergoing hemodialysis and those with a chronic fragile health status, diversion to traditional facilities may place a surge capacity need in a different manner. Traditional facilities will need to be capable of maintaining critical services while also contributing to the community’s surge capacity.

Nontraditional Facilities Arena

The OST³C model uses a rapidly deployable center that would accept patients, either self-referred or transported by ambulance from an explosion or chemical event. It has been suggested that early deployment of local medical centers can alleviate the burden placed on local hospitals.¹⁸ Decontamination facilities may need to be established rapidly to prevent further contamination of the center. Patient care flow in the center directs

patients first to a triage process and then to either a transportation section for transfer to a hospital or to a treatment area for definitive care. The duration of care is anticipated to be relatively brief (24 hours or shorter) and may consist simply of observation for further symptoms. Because most casualties in an acute, rapid-onset event (explosion, structure collapse, or chemical release) will be rapidly transported, the most significant weakness of the OST³C model is the need for rapid deployment and implementation. Therefore, the OST³C facility must be well planned, well integrated, and well rehearsed. This frequently limits its utilization; however, two additional potential roles for such a facility include short-term (12- to 24-hour) observation units and predeployment for large-scale events, such as mass gatherings. Physical requirements include access to controlled vehicular traffic for ambulance use, male and female lockers and shower facilities or an external water supply for outside decontamination, heating and air conditioning, electricity with generator back-up, etc. Potential buildings to be used for an OST³C are gymnasiums, fitness centers, hotels conference centers, and any other building with large space capacity.

The acute care center (ACC) component of the Modular Emergency Medical System (MEMS) provides a care center approach. As described in *Modular Emergency Medical System: Concept of Operations for the Acute Care Center*,¹⁹ the ACC is designed as an organized, equipped, and staffed facility specifically to provide services to those affected by a biological or communicable disease event. It is designed to treat patients who require acute care but not mechanical ventilation for a duration of days to weeks. Patients who require intensive life supportive care would be admitted to a traditional hospital. The ACC would be near a traditional hospital but transparent to the public who should self-refer or be referred to the center’s emergency department for initial evaluation and subsequent triage.¹⁹ However, the ACC also could be integrated into diversion protocols to alleviate emergency departments from this triage function and optimize the ACC’s utility. The ACC module is a 250-bed pod system (5 × 50-bed nursing units) that is expandable to a maximum of 1000 patients and requires 40,000 to 48,000 square feet. Ideal buildings include armories, schools, hotel conference rooms, and community centers. These buildings offer adaptable space, heating and air conditioning, kitchen facilities, adequate plumbing facilities, and power and water supply. They also may supply necessary Internet access.¹⁹

Long-term care facilities (nursing homes, assisted living facilities, and rehabilitation centers) may be available either for acute care patients or for patients who were discharged early from traditional acute care facilities to make beds available for disaster victims.

Special medical needs shelters that focus on attending to people requiring specialized services may allow the healthcare community not only to provide acute services to this population but may also allow for continuing care and domiciliary care for subacute and longer terms of treatment. The need for this type of shelter and the specific resources necessary must be planned for after an assessment of the community, optimally before an event.

Domiciliary Care Arena

Patients who are discharged from a hospital, treated and released home from triage centers, or those being observed at home for symptoms will require specific facility resources. Adequate home care accessories (e.g., wheelchairs, crutches, bandages) may need to be made available. Patients being monitored by public health authorities either for epidemiological information or symptoms will require adequate access to telephone monitoring or access to providers visiting at the home. As required, the homes must be able to provide heat or air conditioning, power, water, a food supply, and the basic needs. If homes are not available, alternative domiciliary care can be provided at locations such as hotels and college dormitories.

There are additional considerations for all of the previously cited facilities. Care should be taken not to identify facilities assumed by other response agencies (e.g., American Red Cross, National Guard Armories). In addition, portable structures, either hard shell or tent type, can be used and provide cost-effective, nonconstruction solutions. The length of use may be affected by the choice of shell, weather elements, and actual use. MOUs with facilities, especially if not publicly held, should be instituted to allow for availability and postevent reimbursement and recovery. Alternatively, adequate legal authority of local or state officials to commandeer facilities must be established and used.

Personnel

During the evolution of the event through to disaster operations, the roles of personnel may change and practice paradigms may shift. Table 28-3 illustrates this shift in roles.

Prehospital Arena

For formal incident scene triage, treatment, and transport, traditional fire/rescue/EMS and other first responder agencies will provide the necessary care. Informal triage and transportation will also be performed by

bystanders and the casualties themselves. The formal resources can be supplemented with community teams, such as the Community Emergency Response Teams (CERTs). The CERT program is an all-risk, all-hazards training in which citizens may initially take actions on their own, and these actions can make a difference. The CERT program was developed by the Los Angeles Fire Department (LAFD) to engage citizen volunteer efforts to augment the response capacity before and during the department's response. In 1993, the Federal Emergency Management Agency (FEMA) made the concept and program available to communities nationwide. The Emergency Management Institute (EMI), in cooperation with the LAFD, expanded the CERT materials to make them applicable to all hazards. In January 2002, CERT became part of the Citizen Corps, a unifying structure to link a variety of related volunteer activities to expand a community's resources for crime prevention and emergency response. As of December 2004, 50 states, three territories, and six foreign countries were using the CERT training for a total of 1900 CERT teams.²⁰

Because of the magnitude of a catastrophic event, such as an explosion, adaptations will be made as MCI operations are instituted. Triage will be abbreviated with use of systems such as the Sacco Triage Method or START (Simple Triage and Rapid Treatment Plan) method, which were both developed for use by rescuers with basic first aid skills to triage patients in 30 to 40 seconds or less. The Sacco Triage Method attempts not only to assign a level of acuity to a patient but also allows available resources to be assigned to the patient. Optimally, treatment will be limited and patients will be transported per MCI protocols.

Central collection points, such as portable triage shelters or the OST³C, can be staffed with personnel other than traditional first responders. Care at these intermediary centers is not expected to be a substitute for that provided in a traditional emergency department; staff should be able to provide, at a minimum, basic life support functions. Individual jurisdictions may decide to staff these centers with personnel who can provide a higher level of care if, for example,

TABLE 28-3 HEALTHCARE PROVIDER ROLES*

PROVIDER	DAILY ROLE	ROLE DURING SURGE
Public health: State and local	Mental health, epidemiological investigations, disease monitoring, alerting, healthcare regulation and oversight, expertise resource, laboratory analysis	<i>Crisis and resource management and coordination, regulatory relief</i> <i>Neighborhood Emergency Help Centers (NEHCs), ACCs, OST³C</i>
Hospitals	Diagnosis and treatment of all patients	Diagnosis and treatment of <i>critically</i> ill patients
Community health providers: Private practitioners, large group practices, community health centers, surgicenters	Care and treatment of noncritically ill patients (general medical and mental healthcare)	Care and treatment of <i>less critically</i> ill patients (minor trauma and surgical patients)
Fire/Rescue/EMS: Public and private	Scene Incident Command System and control Triage, treatment, and transport	Triage, treatment, and transport; <i>greater role in crisis and resource management and coordination</i>

*The roles of providers may shift as the event unfolds and evolves. This table reflects (in italics) new or differences in roles that may be required of providers.

screening and dispensing of prophylactic antibiotics or vaccinations are to occur. Several models are offered for establishing a triage and dispensing site, optimizing personnel resources, and projecting the number of persons to be vaccinated or dispensed medicines.^{21,22} The Bioterrorism and Epidemic Outbreak Response Model (BERM)²³ provides a computer model for determining the number and types of personnel necessary for such a clinic site and can be used for planners to provide adequate resources. Most dispensing site plans are based on the medical model and, therefore, provide for some degree of triage for ill patients. It is anticipated that these providers will be public health and community volunteers because hospital employees will be occupied in their respective facilities.

Additional resources available for “prehospital” arena care include those involved with volunteer corps, disaster medical assistance teams (DMATs), and the Metropolitan Medical Response System (MMRS). These resources allow for reliance on personnel responding directly to the emergency rather than staff required to report for duty at traditional facilities.

A federal DMAT, which is part of the National Disaster Medical System (NDMS), is a group of medical and support personnel designed to provide emergency medical care during a disaster or other unusual event at a location usually remote from the origin of the team. DMATs deploy to disaster sites with adequate supplies and equipment to support themselves for 72 hours and provide medical care at a fixed or temporary medical site. They may provide primary healthcare and/or augment overloaded local healthcare staff. DMATs are designed to be a response element to supplement local medical care until other federal or contract resources can be mobilized or the situation has resolved. Each DMAT deployable unit consists of approximately 35 individuals; however, teams may consist of more than three times this number to provide some redundancy for each job role. This ensures that an adequate number of personnel are available at the time of deployment. A team is composed of medical professionals and support staff who are organized, trained, and prepared to activate as a unit. Some states and regions are developing intrastate DMATs or Medical Reserve Corps. In a large-scale disaster, a DMAT’s ability to provide local personnel surge capacity may be limited because these teams frequently draw on the same pool of professionals already expected to respond during the disaster.

The MMRS, directed by U.S. Department of Homeland Security and FEMA, directly supports enhancement of existing local first responder, medical, public health, and

emergency management by increasing systematic, integrated capabilities to manage a weapons of mass destruction MCI until significant external resources arrive and are operational (typically 48 to 72 hours). The program provides training, supplies, medical caches, and coordination within a metropolitan jurisdiction. It does not supply additional personnel but provides an organizational structure and resources for response in a region. There are 125 MMRS operations in the United States.

Traditional Facilities Arena

Care of patients at traditional facilities may require additional resources, the reappportioning of staff to different staffing patterns, etc. Relative to the amount of surge capacity within the hospital, planners could calculate the number of necessary additional staff as follows:

$$168 \text{ hours per week} \div 40 \text{ hours per week workload} = 4.2 \text{ full-time equivalents (FTEs)}$$

Each staff position requires 4.2 FTEs for 24-hour operations, 7 days a week.

If a 1:4 staff-to-patient ratio is maintained, then:

$$\begin{aligned} (\text{No. of surge beds} \div 4) &= \text{No. of staff positions} \\ (\text{No. of staff positions}) \times (4.2 \text{ FTEs}) &= \text{No. of additional healthcare providers necessary per week} \end{aligned}$$

If a 1:6 staff-to-patient ratio is maintained, then:

$$\begin{aligned} (\text{No. of surge beds} \div 6) &= \text{No. of positions} \\ (\text{No. of staff positions}) \times (4.2 \text{ FTEs}) &= \text{No. of additional healthcare providers necessary per week} \end{aligned}$$

If a 1:10 staff-to-patient ratio is maintained, then:

$$\begin{aligned} (\text{No. of surge beds} \div 10) &= \text{No. of staff positions} \\ (\text{No. of staff positions}) \times (4.2 \text{ FTEs}) &= \text{No. of additional healthcare providers necessary per week} \end{aligned}$$

Table 28-4 presents the calculated staffing needs for the various staffing ratios calculated for the regional surge beds presented in Table 28-1.

An additional staff resource to hospitals is a pre-established system of volunteers. Healthcare provider volunteers who are not full-time employees, who are retired, or who are no longer in clinical practice but maintain a license may be available for emergency staffing. Volunteer management programs must provide for the recruitment, confirmation of credentials, emergency notification/ deployment, and training/orientation of these valuable individuals. Individual healthcare entities

TABLE 28-4 ADDITIONAL STAFF REQUIRED FOR SURGE

	POPULATION	SURGE (BEDS/PATIENTS)	HEALTHCARE PERSONNEL (1:4)	HEALTHCARE PERSONNEL (1:6)	HEALTHCARE PERSONNEL (1:10)
State A	5,595,211	2798	2938	1958	1175
Region A	2,571,695	1286	1350	900	540
City A	628,670	314	329	220	131

must decide whether to accord any particular healthcare worker emergency privileges to practice in facilities for which it has responsibility. Approaches include accepting the credentials maintained by other accredited healthcare facilities during an emergency into facility emergency preparation plans, relying on government programs that develop volunteer medical corps, and/or establishing mutual aid agreements. The Emergency Systems for Advance Registration of Volunteer Health Care Personnel (ESAR-VHP) is an additional step to provide for coordinated emergency increases in staffing of physicians, nurses, pharmacists, behavioral health professionals, emergency medical technicians, and other appropriate healthcare professionals. The ESAR-VHP system, still in development, would establish a regionally accepted, standardized advanced registration system for healthcare professionals through collaboration of hospitals, licensing boards, professional organizations, etc.

Managing the number of spontaneous volunteers by providing rapid credential verification and logistic requirements increases organizational burdens. Providing adequate coordinated efforts for volunteers and integrating these well-intentioned and needed individuals would yield positive results for all parties.

Nontraditional Facilities Arena

Once the provision of care is shifted or augmented to a nontraditional facility, the targeted reserves of healthcare providers likewise shifts away from those in traditional hospitals. Out-of-hospital primary providers, public health providers, volunteer corps, DMATs, and other federal assets will be relied on to deliver care in these locations. In addition, nongovernment agencies, such as the American Red Cross Disaster Relief Services and Salvation Army, may deliver care. A pre-event inventory of agencies, type of care provided, and number and identity of providers must be conducted to provide a responsible plan without “double counting” assets. For example, the use of National Guard medical personnel may be a pivotal piece of a community’s plan. However, many of these personnel are also providers at local hospitals or may become an essential federal asset and may not be accessible for local response.

It is recommended in the ACC model to have the following minimal staffing per 12-hour shift for a 50-bed nursing subunit:

- Physician (1)
- Physician’s assistant (PA) or nurse practitioner (NP) (physician extenders) (1)
- Registered nurses (RNs) or a mix of RNs and licensed practical nurses (LPNs) (6)
- Nursing assistants/nursing support technicians (4)
- Medical clerks (unit secretaries) (2)
- Respiratory therapist (RT) (1)
- Case manager (1)
- Social worker (1)
- Housekeeper (1)
- Patient transporter (1)

The minimal number of staff providing direct patient care on the 50-bed nursing subunit per 12-hour shift is

12, which includes the physician, physician extenders, nurses, and nursing assistants.

While the absolute number of providers necessary changes as the event progresses from “emergency operations” to “disaster operations” so, too, do the roles change. As illustrated in Table 28-3, as “disaster operations” and aggressive diversion are implemented, community providers may be tasked with providing care to the less critically ill and injured patients, whereas the hospital providers will be responsible for the more critically ill and injured patients.

Domiciliary Care Arena

Domiciliary care will, of necessity, require case management. This case management may be provided by several resources at various stages of the event and the patient’s course. If the patient is hospitalized, the case management through hospitalization and through to discharge may be assumed by the facility. However, if the person is never hospitalized or is discharged from a facility, public health, community practitioners, etc., may be responsible for assuming this role. A pre-event inventory of resources for domiciliary care will reveal what currently exists in a community, what the needs may be, and any gaps that will occur during a disaster, which may be addressed through preparedness activities.

Public health authorities will be engaged in the epidemiological investigation, including case investigation and case contact. They are also likely to be responsible for the monitoring of symptoms and the initiation and maintenance of quarantine in communicable disease outbreaks. In addition, public health agencies typically provide telephone hot lines with information for providers and the general public. In Toronto, 225 residents met the case definition of SARS. Toronto Public Health investigated 2132 potential cases of SARS, identified 23,103 contacts of SARS patients as requiring quarantine, and logged 316,615 calls on its SARS hot line.²⁴ Temporary suspension of nonessential services may result in additional public health personnel; however, a long-term event will require regular re-evaluation of the need to reinstate these services.

Providers of domiciliary care may come from professional and nonprofessional resources. Home health agencies and nongovernment agencies, such as the American Red Cross, may be available and have capacities to provide professional level services. Basic services, such as oral hydration, dressing care, and activities of daily living, may be provided by community-based formal and informal networks. Families, churches, and community organizations can be engaged to deliver such services and may be willing to do so, provided they are given the resources, minimal-but-meaningful education, and appropriate protection to do so. Pre-event outreach can organize these groups and allow for adequate support.

Medications and Supplies

Medications and supplies are commonly regarded as a short-term need and vulnerability. In fact, in a long-term event, such as a communicable disease event, supply shortages may become an increasing and broader issue. A disas-

ter may quickly exhaust available supplies, including medications, or may prevent the further replenishment of supplies from outside of the affected area. It is important to conduct a needs assessment and have an ongoing materials management process to assess current and anticipated needs and acquisition and appropriation of supplies on hand. In many U.S. disasters, supply shortages have not occurred, but rather, excessive donations have created a different challenge (see Chapter 35). Unfortunately, the prevent purchase and stockpile of equipment can be costly and difficult to justify in the current economic environment and as healthcare facilities continue to shift to “just in time” inventories. Graded increases in par levels of supplies, regionally leveraged purchases, and rotation into stock can ease the financial burden of preparedness. Federal response systems anticipate this need and purchase, and strategic forward deployment has been under way at that level. However, depending on the nature of the incident, it is prudent to assume that facilities and agencies should plan on being self-sufficient for the first 48 to 72 hours after an event. This places an additional burden on planning for an event, such as an explosion or chemical event, which will require adequate resources within the first hours or sooner. In this case, outside resources should be used to provide subsequent care and to restock used supplies.

If additional supplies are warehoused at central locations, numerous factors will need to be taken into consideration, including apportionment decisions, speed and mechanism of delivery, and access to delivery location. Limited material supplies may not meet demands, and an apportionment policy should be decided on before an event to allow for dialogue, education, and evidence-based decisions by officials. The speed and mechanism of delivery may vary, depending on the incident. Natural disasters may impede surface transportation of surge supplies. During the Sept. 11, 2001, attack on the Pentagon, emergency response vehicles, police closing of roads, and the ordered evacuation of federal facilities created a transportation gridlock, limiting the delivery of anticipated supplies to some hospitals in the District of Columbia (MedStar Health System, personal communication, January 2004).

Adequate personal protective equipment (PPE) for the anticipated surge capacity staff will be necessary to maintain a healthy staff. Depending on the nature of the event, the type of PPE used will likely be the most protective until the causative agent is defined. Standards for such PPE are well defined by the Occupational Safety and Health Administration. In disasters with noncontaminated physical hazards, such as an earthquake with building collapse, PPE should consist of protection for the extremity, head, ears, and eyes. In the prehospital arena, for suspected chemical, contaminated explosive, or unknown contamination scenes, personnel functioning within a “hot zone” are likely to be in Level A protection. Level A PPE offers the highest level of protection. It encompasses positive pressure breathing apparatus, SCBA, with a fully encapsulating chemical suit. After the removal of victims and subsequent decontamination, graded “step-down” in protection can be made until a level appropriate for definitive protection is attained. For example, initial evaluation of patients with an unknown communicable disease may

first be approached with the provider in full high-efficiency particulate air (HEPA) respiratory and splash precautions. Once the infectious agent is identified and other potential preventative steps are taken (e.g., vaccination), PPE can be shifted to the appropriate mask and Universal Precautions. Amounts of PPE required to sustain a response is dependent on the durability and lifespan of the equipment (single-use versus multi-use), inter-user transfer of equipment (sharing), and the anticipated number of changes per provider. Durable hazardous materials gear may have longevity of several days into an event, may be able to pass from one worker to another, and is not necessarily disposable after each use. N95 respirators used for smallpox respiratory protection may be usable by a single user over a 12-hour shift but would *not* be shared and would be disposed of after the shift. Estimation of PPE requirements can be made by the following formula:

$$\text{No. of personnel per day} \times \text{No. of exchanges per day per person} = \text{No. of anticipated PPE sets per day}$$

Medical supplies such as antibiotics, chemical antidotes, bandages, and splints can be maintained at traditional facilities and/or cached at central locations. Anticipating the number of needed supplies will depend on the anticipated surge needs and will likely be proportionate to those needs. Adjustments will need to be made with materials managers’ assistance to accommodate differences in durable and non-durable goods. Additional resources include prepositioned caches in traditional first responder agencies (police, fire/rescue/EMS) and in agencies such as emergency management agencies and public health agencies. Deployable assets such as the Strategic National Stockpile, the CHEMPAK program, DMATs, and MMRS, have caches of medical materials not only to sustain the function of the teams but for treatment of casualties and patients. There are numerous community resources that should be inventoried and may be available for use. Pharmaceutical vendors, veterinary pharmacies and practices, dentists and dental supply warehouses, etc., may have supplies that are usable and available. Planning for use should include emergency procurement plans, apportionment policies, and MOUs with these entities to expedite postevent recovery.

Delivery of essential supplies such as power, food, and water must be considered for those people who, because of their injuries or illnesses, cannot access these services on their own. Traditional formal disaster relief services, such as the American Red Cross and Salvation Army, and nonformal services, such as community and faith-based groups, should be integrated so that patients in domiciliary care are identified to them and the organizations are part of an individual’s case management plan.

Legal and Policy Issues

Policy development and decisions, to the extent possible, are best made or planned for in the pre-event stages when level heads prevail; there is the ability to adequately review current literature and science; and dialogue, debate, and education can be accomplished.

Triage, treatment, and transfer protocols; mutual aid agreements; and credentialing programs will require the input and review by legal counsel. Additional statutory

and regulatory changes may need to be sought to provide the bases for emergency powers of officials, medicolegal protection as practice paradigms shift, and compensation and liability for surge personnel.

Aggressive diversion of patients described earlier raises several critical legal concerns and questions. Issues related to malpractice liability, state regulations, and the Federal Emergency Medical Transfer and Labor Act (EMTALA) must be well researched and addressed.

EMTALA provides for, among other items, adequate screening before patient transfer, maintenance of level of care during transfer, and an accepting physician at the receiving facility. Triage away from a facility without well-established protocols that have been reviewed and approved by legal authorities will result in unwelcome anxiety and noncompliance by healthcare providers. During *nationally* declared disasters, EMATLA regulations may be suspended by authorities, but during *local* or *state* disasters, they will be in force.²⁵

Even with effective planning and use of resources, an overwhelming event may outstrip resources and result in the re-evaluation and acceptance of a degradation of the standards of care. Serious discussions of this potential must be conducted before an event, not only with policy makers and legal experts but also with the general public.

CONCLUSION

Overall, the goal of surge capacity planning is to provide a series of prepositioned processes to ensure the delivery of appropriate care with appropriate resources in a graded, phased response. A potentially overwhelming response can be planned and provided for with adequate assessment of the population's needs and community resources and the development of plans for matching these needs with resources, augmenting as necessary. Planning may not necessarily include large capital expenditures but will provide stimulus for creative collaborative processes. The integration of disciplines and practices is essential because no single healthcare component can shoulder this alone. Integration of the general public through to multiple government agencies in response to a disaster will ultimately provide for an overall surge capacity.

chapter 29

Operations and Logistics

David Jaslow

Effective disaster management relies on the ability of responding organizations or personnel to organize themselves into cohesive work units under a defined leadership structure that can coordinate with each other to meet specific goals and mitigate the disaster. One of the hallmarks of a developed country from the emergency response perspective is its ability to effectively respond to and manage a complex disaster event in an organized fashion.^{1,2}

The terms “operations” and “logistics” refer to two of the five management functions that compose the foundation of the Incident Command System (ICS). This terminology is also used to describe the actual components or work units that accomplish specific tasks at a disaster event. Such terminology has now become commonplace, and it is routinely used to describe identical functions at local or regional emergency incidents, not just disasters.

The operations section is responsible for taking a set of incident objectives that the incident commander has developed and designing a strategic plan to mitigate the disaster incident and its consequences. Such a plan necessitates organization, assignment, and supervision of tactical resources, all of which are housed in the operations section. The logistics section is responsible for services and support needs, which are necessary to sustain the tactical objectives of the operations section. In simple terms, the logistics section is the “go to” function for any wish list of equipment, personnel, or services necessary to support disaster response operations. Even though operations and logistics are two completely separate functions and functional entities, the efficiency and effectiveness of an operations sector at a major incident are due in some degree to a well-organized and properly functioning logistics sector, much like the relationship between a race car driver and his or her pit crew.

HISTORICAL PERSPECTIVE

Federal response to disasters in the United States probably goes back to an 1803 act of Congress that made provisions available to New Hampshire after a devastating fire. Obviously, the federal government has grown considerably since then and has increased and codified the

response to disasters. It is important to state that, like most laws in the United States, provisions for disaster response, like the provision after the New Hampshire fire in 1803, are reactive and not proactive. Myriad laws and acts such as the Flood Control Act and the Fire Response Act resulted in a relatively fragmented approach to federal disaster response in which a disaster required response from literally hundreds of agencies until the enactment of the Robert T. Stafford Disaster Relief and Emergency Assistance Act in 1974.² To further unify the federal response to disasters, the Federal Emergency Management Agency (FEMA) was established in 1979 under President Carter and was charged with coordinating federal disaster response.

Even though disaster response is often legislated at the federal level, response and coordination of deployed resources historically have fallen on the jurisdiction legally responsible for the location in which the disaster occurs. In other words, like politics, all disasters are “local,” or at the very least, start out as “local.” In most jurisdictions across the United States, the fire chief (or his designee) of the authority having jurisdiction (known as the AHJ) becomes the *de facto* incident commander at an event that involves imminent danger to life or property, with the exception of purely law enforcement-related situations (e.g., sniper, hostage situation), regardless of training, experience, abilities, knowledge, or competence in responding to major incidents. It is the incident commander who has overall authority for disaster operations, regardless of the size or scope of the disaster, unless or until he or she transfers command to another individual.

For many decades, the standard practice among incident commanders who determined that they lacked the resources to manage an incident was to summon additional manpower supplies, equipment, and emergency vehicles from neighboring communities as quickly as possible. This concept is known as *mutual aid*. Mutual aid compacts or agreements are drawn formally or informally between individual agencies or political jurisdictions, but there is still no national mutual aid system or standardized guidelines for how to develop such a plan in the United States. In more progressive fire-rescue systems, mutual aid resources are dispatched according to a predefined algorithm or plan, and this concept is known

as *automatic aid*. One of the greatest challenges of developing mutual aid systems has been to overcome the “more is better” philosophy in the fire service, which leads to large amounts of resources dispatched to a disaster regardless of whether they are proper, necessary, or even requested. This is a particularly thorny issue in regions of the country covered by mostly volunteer departments.

If regional resources do not satisfy the needs of a disaster response, the traditional next step has been to request aid from the state Emergency Management Agency. Governors can declare a state of emergency, which releases materials and financial resources and activates the National Guard. Only in the last 10 to 15 years have many states developed unique specialty response teams capable of mobilizing for disaster response, such as urban search and rescue (US&R) and hazardous materials/weapons of mass destruction (WMD) task forces, emergency medical service (EMS) strike teams, and similar entities. In 1996, Congress enacted the Emergency Management Assistance Compact, a mutual aid agreement that allows human and material resources to cross state lines and operate in a declared disaster situation when requested through the proper channels and approved by the governor of the affected state.

There was no coordinated federal contribution or response to disaster operations and logistics support until the creation of FEMA in 1979. This agency is charged with responding to, planning for, recovering from, and mitigating against disasters. Despite the creation of this agency, it was not until problematic response to several large-scale disasters, including hurricanes Hugo and Andrew and the Loma Prieta earthquake, that FEMA's role in disaster operations and logistics became better defined and coordinated. James Lee Witt, FEMA director under President Clinton, is largely credited with the transformation of the agency from an organization that predominantly handled the recovery phase of a disaster to one that took on a prominent role in the response phase.

CURRENT PRACTICE

Operations

Most disaster response begins with a call to 911, and police or fire personnel are the first responders to the disaster. Those first on-scene begin the initial response that will most typically include assessing the possibility for immediate mitigation and then summoning more resources and setting up an initial Emergency Operations Center (EOC) or command. Even though they will be few, first responders will bear the responsibility for initially assessing the scope and extent of the disaster until more resources arrive. When more resources arrive, the first priority will be to effect mitigation to save lives immediately in danger, but soon after, priorities will grow to include making an assessment of the potential short- and long-term consequences of the disaster; determining the need for resources beyond the local jurisdiction, including state and federal; and organizing an ICS.

Disaster operations increase in size and complexity depending on the nature of the event; duration of the event; and resources, which are necessary to stabilize the incident. Common tactical resources at a disaster incident include fire suppression, technical rescue, hazardous materials containment, and EMS, to name a few. Exactly what kind and quantity of resources will be necessary to deploy at a disaster event depends on the nature of the event and the tactical objectives set by command personnel.

The ICS, discussed in greater detail elsewhere in this textbook, is the national standard for management of personnel and operations at an emergency incident of any size or complexity. ICS is a flexible management structure, which allows for expansion and contraction of all sectors, including operations, based on the dynamics of the incident. In late 2004, the Department of Homeland Security released the National Incident Management System (NIMS) as a template to complement ICS. NIMS builds on the concept of a unified command structure and provides a framework for interoperability and compatibility among various public and private organizations that respond to large-scale disasters within the United States.

The operations section chief is the individual designated by the incident commander to manage and command the operations section and who is ultimately responsible for developing and implementing strategies and tactics to meet the incident objectives. Tactical decision-making (i.e., how, when, and where to deploy certain resources to mitigate a disaster) is the responsibility of the operations section chief. However, the ability to make these decisions in a competent fashion is predicated on a continual flow of information both from the field and from the command sector. If an incident spans more than one operational period (usually one work cycle), the operations chief may assign a deputy to work the opposite shift to ensure adequate time for nourishment and rest.

There are several very difficult obstacles to overcome when establishing a robust operations section during disaster response. Personnel from different agencies may not be accustomed to working together or may not speak the same response vernacular. Communications systems may be different among responding agencies. Tactical objectives may be accomplished differently by different agencies or resource types. Another often-misunderstood pitfall is the influence of politics and egos that may tend to drive decision-making despite the known dangers, which these behaviors engender.

From a field perspective, there are several goals that the operations chief must accomplish during the initial stages of the response to a disaster. First, he or she must develop an incident action plan (IAP). This plan details the objectives of the mission and how they will be met. An IAP should be written for every operational period during the disaster. Second, the operations chief must decide how much to expand his or her organizational structure. Supervisory personnel should be titled and placed in charge of subsidiaries within the operations section based on who is most qualified to perform the task rather than on a person's rank or predisaster title.

Span of control should not exceed seven personnel in the organizational structure. Third, the operations chief must decide in conjunction with the incident commander and safety officer what degree of risk he or she is willing to assume when sending emergency responders into an unstable environment to perform search, rescue, evacuation, medical care, and mitigation activities related to the disaster event. Fourth, the operations chief must maintain an effective line of communication with the various components within the section as well as with the other ICS sections and the incident commander. Fifth, the operations chief must understand the concept of flexibility when making decisions. Disaster events may appear static to the civilian population, but emergency responders understand that these events are dynamic in nature. Changing environmental conditions, secondary hazards, fatigue, resource availability, and many other factors contribute to ever-changing disaster conditions, and these conditions require adaptability and flexibility in decision-making by those whose job is it to mitigate the incident.

Expansion of the operations section of the ICS is usually a rare event during local emergencies. However, an event that the Department of Homeland Security labels an “incident of national significance” may necessitate creation of divisions, groups, branches, task forces, and strike teams. These entities represent functional and geographical separation of duties. Such was the case at the 2001 World Trade Center disaster. The Fire Department of New York (FDNY) retained command and control of the entire incident and eventually developed a unified command structure according to principles of the ICS. The 16-acre size of the disaster site required a large-scale expansion of the operations section. Divisions were created according to street names that bordered the scene. Groups included functional components such as technical rescue, fire suppression, and EMS. Branches of each group were composed of personnel attached to a specific type of resource, such as the US&R branch. Within the US&R were individual US&R task forces. EMS strike teams from FDNY and surrounding mutual aid organizations were deployed in support of US&R task forces and other specialized resources.

A variety of federal resources are available to assist local incident commanders in handling large-scale disasters and their aftermath. Such resources and directions for their interaction and coordination can be found in the National Response Plan (NRP), which debuted in December 2004. The NRP aligns federal coordination structures, capabilities, and resources into a unified, all-discipline and all-hazards approach to domestic incident management. An outline of the contents of the NRP can be found in Box 29-1.

Two of the most common emergency response resources deployed from the Department of Homeland Security are US&R task forces and disaster medical assistance teams (DMATs). US&R task forces specialize in response to collapse of reinforced concrete buildings, and their primary mission is to rescue persons trapped in confined spaces regardless of the etiology of the event. DMATs are mobile field hospitals staffed with a

BOX 29-1 NATIONAL RESPONSE PLAN CONTENTS

- Incident annexes

multidisciplinary team of healthcare professionals that can provide medical care for prolonged periods when local infrastructure is incapacitated. Additionally, there are specialized DMATs for the care of children, burns, victims of WMD incidents, animals, and deceased persons.³

Logistics

Typical logistics functions during a disaster include obtaining, maintaining, and tracking essential personnel, supplies, and equipment; providing communications hardware and installation of communications systems; setting up food services; setting up and maintaining incident facilities such as dining halls, the incident command post, and bed-down areas; obtaining necessary transportation resources for personnel and supplies; and providing medical services to incident personnel. The size, duration, and specific needs of an incident dictate whether a separate logistics functional element must be created within the ICS. Most disasters, by definition, meet the criteria that any incident commander would use to establish a logistics section. Essentially, the logistics section, or function, is to figure out how to get what is needed and get it to where it is needed. An often daunting function, there are many examples from history that show us the difficulty of getting what is needed, but more often than not, it is getting the required resources, including manpower, to the needed place that proves the most challenging.

The logistics section chief manages and commands this section and is ultimately responsible for its performance. If an incident spans more than one operational period (usually one work cycle), the logistics chief may assign a deputy to work the opposite shift to ensure adequate time for nourishment and rest.

The logistics section is typically divided into two branches: service and support. Units located within the service branch provide direct service functions that require human interaction, including communications, medical care, and nourishment. The support branch is composed of functions that typically do not involve human interaction, such as vehicles and transportation, supplies, and facilities.

The medical unit located within the service branch of the logistics section warrants special attention since it is often confused with the delivery of routine EMS at a large-scale incident. Emergency medical functions fall within two distinct categories in the ICS. EMS is typically a branch within the operations section. The responsibility of the EMS branch is to provide emergency medical care and treatment to victims of the disaster. The medical unit is designed only to provide

emergency medical evaluation and treatment to disaster responders.

This is an important distinction, both theoretically and functionally. The medical unit is akin to the rehabilitation, or “rehab,” sector at a fire scene. The goal of the rehabilitation sector is to monitor firefighters and other emergency response personnel for signs and symptoms of physical and psychological stress induced by the incident. These conditions are usually successfully mitigated with hydration, nutrition, and rest. The rehabilitation sector is a separate function from the treatment sector established by EMS personnel to treat victims of the fire itself. At a disaster scene, the victim treatment area and the responder treatment area should be physically separate, especially since responders do not typically require medical treatment per se and will have difficulty recuperating amidst the chaos of a victim treatment area.

The logistics section chief works closely with the chiefs of planning and finance/administration. He or she monitors the incident action plan because it provides valuable information about what supplies and equipment may be necessary as the disaster event progresses and as incident objectives change. The logistics section chief is also mindful that supplies and equipment may have to be contracted and purchased or bartered. Thus, the logistics section chief must interact frequently with his or her counterpart in finance/administration since lack of funding may have a direct impact on the performance of the logistics section.

Massive relief operations, such as was seen during the response to the Southeast Asia tsunami disaster of 2004, provide insight into why logistics is such an important part of disaster response. Described as a “logistics nightmare” by United Nations personnel, the response to the tsunami disaster of unprecedented proportions was quite complicated, especially considering the difficulties with the development of a unified command structure among representatives of state and nongovernment agencies from different countries. At one point early in the response, flights to an airport in Indonesia had to be suspended because there were too many airplanes already on the ground that were unable to unload their cargo due to lack of space at the airport; this was due to ineffective ground transportation to deliver the goods to the end user. This problem, in turn, was partially a result of a lack of vehicles and partially a result of the inability for the available vehicles to reach certain areas due to wash-out of the roadways.⁴ Ironically, the biggest ongoing logistical challenge in the response to the Southeast Asia tsunami was how to distribute the abundance of supplies and funding. Similar problems have occurred in various disaster events in the United States during the past 20 years.

The Operations Support Directorate (OSD) exists within FEMA to provide the agency with logistics, security, health and safety, and other mission support services essential to the accomplishment of the agency’s all-hazards management program (Box 29-2). FEMA’s Mobile Operations Division includes five regional Mobile Emergency Response Support (MERS) detachments and the Mobile Air Transportable Telecommunications System. MERS provides a large fleet of specialized vehicles and dedicated personnel to deliver food, water, fuel, sophisticated com-

BOX 29-2 RESPONSIBILITIES OF FEMA’S OPERATIONS SUPPORT DIRECTORATE

- Logistical support in the areas of agency-wide logistical systems, disaster support facilities operations for FEMA, and the agency’s emergency management partners
- Protection of personnel, facilities, and equipment to ensure a secure environment for FEMA and its emergency management partners
- The agency-wide Occupational Safety and Health Program
- The FEMA mitigation program for employees
- Numerous essential mission support functions, such as printing, graphics, storage, and distribution of FEMA publications, forms, and records; management program; space management; and procurement of operational supplies, equipment, and services

munications capability, and other logistics support wherever needed. These resources support local, state, and federal emergency responders, not disaster victims.

PITFALLS

Management of large-scale disasters is fraught with difficulty despite the fact that most problems are predictable and recur at every major disaster to some degree (Box 29-3). There is no disaster incident in which everything goes according to plan. The ability of the incident commander and the operations and logistics chiefs to be flexible in decision-making, delegate authority when necessary, and adapt to changes in incident conditions and mission priorities is essential.

Most communities have developed fairly comprehensive emergency management plans to address the hazards in their region. However, too often these plans lack a significant public health and medical component or that component is poorly defined in terms of what its relationship is to the overall disaster incident. Drs. Joe

BOX 29-3 PARTIAL LIST OF FACTORS ASSOCIATED WITH INEFFICIENT OR INEFFECTIVE DISASTER OPERATIONS

- Lack of accountability, including inadequate supervision and ambiguous or absent chains of command
- Poor communications due to inefficient uses of available communications, failure of and lack of redundancy in communications systems, and conflicting codes and terminology
- Lack of an orderly, systematic planning process
- No common, flexible predetermined management structure to enable delegation of responsibilities and manage workloads efficiently
- No predefined methods to integrate interagency requirements into the management structure and planning process effectively
- Inability to control access to the disaster site, to manage a large influx of unsolicited disaster volunteers, and to curb “freelancing” among emergency response personnel
- Difficulty in coordinating, tracking, and documenting human and materials resources

Barbera and Anthony MacIntyre, disaster medicine experts from George Washington University, designed a comprehensive model for the management of mass casualty incidents as well as more routine emergency incidents, which have predominantly a health and medical focus. The Medical and Health Incident Management (MaHIM) System describes an “overarching system for organizing and managing the many diverse medical and public health entities involved in mass casualty response.” It is based on principles of public health and emergency management and attempts to point out the community approach to problem-solving and emergency response in the setting of a mass casualty incident rather than the individual response of an EMS service, hospital, or public health department.⁵ The MaHIM can be found at: www.gwu.edu/~icdrm/publications/index.html.

CONCLUSION

The United States has long set the pace among developed countries in emergency response to catastrophic incidents, perhaps because it has successfully merged many principles of organizational behavior, emergency medicine, and emergency management. Coordination of emergency responders, development of a unified command structure, tracking of resources, and maintenance of functional communications systems remain challenges that will meet us at every disaster event. The NIMS and the NRP represent the federal government’s most important

contributions to improving disaster response and logistics capabilities in the last decade. Anticipation of pitfalls in disaster response and logistics support and development of adequate contingency planning may be the most important lessons to teach to those who will fill command and leadership positions at a disaster incident.⁶ Individuals who wish to learn more about disaster response, the ICS, NIMS, or the NRP can complete self-study courses created by FEMA at <http://www.training.fema.gov/emiweb>.

The Incident Command System

Nicholas Sutingco

Many incidents, whether major disasters or minor accidents, often require a coordinated response from a variety of agencies along with an established system of command and control. The Incident Command System (ICS) was created to be used at the scene of emergencies and has become a model tool for command, control, and coordination of an effective emergency response. ICS applies leadership and business principles to emergency response command to improve efficiency and effectiveness. The ICS is designed to organize people and resources and to activate necessary services during an emergency response while providing an easily recognizable and accepted organizational structure that can be used for a variety of incidents. Overall, the ICS provides a means to coordinate the efforts of individual agencies as they work toward protecting life, property, and the environment—all while ensuring the efficient, safe use of resources.

Federal law requires the use of ICS for response to hazardous materials (HazMat) incidents. In fact, many states are adopting ICS as their standard system for responding to all incidents. ICS is also promoted by national organizations, such as the Federal Emergency Management Agency (FEMA) and the National Wildfire Coordinating Group, and has been adopted by the National Fire Academy as its standard for incident response. In addition, the ICS is endorsed by the American Public Works Association and the International Association of Chiefs of Police. It was also included in the National Fire Protection Association's (NFPA) 1995 *Recommended Practice for Disaster Management (NFPA 1600)* and is also a part of the National Interagency Incident Management System (NIIMS).

HISTORICAL PERSPECTIVE

In the fall of 1970, Southern California was devastated by a number of wildland fires that burned more than 6 million acres. After 13 days, 772 structures and 16 lives were reported lost.¹ In a report on the overall emergency response to this disaster, numerous coordination problems were identified. Consequently, Congress funded a consortium of state, county, and city fire departments, led by the U.S. Forest Service, to investigate and

address these problem areas. This consortium was known as the Firefighting Resources of California Organized for Potential Emergencies (FIREScope). The consortium identified several recurring problems involving multiagency responses, including nonstandard terminology, nonintegrated communications, lack of consolidated action plans for designated facilities, and an inability to expand and contract as required by the situation.¹ Efforts by FIREScope to address these problems led to the development of the original ICS model for incident management.

ICS later evolved into a system that is now essentially an “all-hazards” tool appropriate for all types of fire and nonfire emergencies. Much of the success of ICS can be attributed to its flexible yet standardized organizational structure and set of procedures. Not surprisingly, users of the ICS have found it to be useful and widely adaptable in a variety of large-scale emergencies and incidents. Over the years, the original FIREScope ICS has been modified and adapted in numerous ways by many, resulting in a number of variant systems. These variants may indeed be easier to use, but their application in large-scale incidents, such as earthquakes and floods, often falls short when compared with the original FIREScope ICS.

Individual communities often have slightly different approaches toward emergency planning and response. Coordinating various communities during a large-scale incident can be complicated by existing differences. Again, ICS use has evolved by incorporating new emergency management concepts into the municipal Emergency Operations Center (EOC) to allow for an easier application of the original ICS model. As a result, more local governments are using the ICS to organize and manage their emergency responses.²⁻⁶ On a different scale, several hospital models exist. However, an increasingly popular configuration is the Hospital Emergency Incident Command System (HEICS).

In 1987, the Hospital Council of Northern California completed work on an adaptation of the ICS to hospital emergency response functions. In a publication entitled *Earthquake Preparedness Guidelines for Hospitals*, ICS principles were used in a system intended to unify hospitals with other emergency responders.⁷ That document in particular served as a

cornerstone in the development of the original HEICS, written by Orange County (Calif.) Emergency Medical Services in 1991. Since then, there have been three editions of HEICS; however, all original attributes, steeped in ICS basic principles, remain as before. HEICS is discussed later in the chapter.

CURRENT PRACTICE

No disaster or emergency is ever the same. Likewise, no one emergency management tool is perfect for all types of incidents. With this in mind, it is not surprising that the major desirable factor in an effective emergency management tool is its flexibility—its ability to be modified to meet the needs of different circumstances without losing compatibility with the entities involved. It also must be effective regardless of the size of incident. Some fire departments use the ICS in nearly every response.^{5,6} In so doing, these departments become more familiar with its application. Users become more comfortable with the system, and when applying it in its larger scope during a larger incident, a resource-intensive emergency becomes relatively simpler.

The original ICS organization is built around five major components: command, planning, operations, logistics, and finance/administration (Fig. 30-1).⁸⁻¹⁰

These five components are present at every incident—from a routine emergency to a major disaster response. In small-scale incidents, these five major components may be managed by the incident commander (IC) alone. In larger-scale incidents, it may become necessary to set up each component separately, with a leader for each component (a section chief) reporting directly to the IC. All incidents, regardless of size or complexity, will have an IC who is ultimately responsible for the execution of each of these five basic ICS activities. The IC is able to expand or contract the ICS organization as required by the situation.

Command Function

The command function is under the immediate authority of the IC. Responsibilities of the IC include the following⁸⁻¹⁰:

- Establishing command and developing an appropriate organizational structure
- Establishing the incident command post (ICP), where primary command functions are executed
- Developing and implementing the incident action plan (IAP)
- Preserving life and property

- Managing resources, including personnel
- Establishing and supporting effective communications with outside agencies (this includes the EOC, when it is activated)
- Ensuring responder and public safety
- Maintaining accountability for task accomplishment
- Authorizing the release of information to the media
- Keeping track of incident finances

As the incident grows in complexity, the IC may find it necessary to delegate authority for performing some of these activities. When such expansion of the command function organizational structure is required, the IC can establish the following command staff positions (Fig. 30-2)⁸⁻¹⁰:

- The information officer deals with the media, coordinating the release of information, alongside the public affairs office at the EOC.
- The safety officer assesses and monitors safety conditions and develops plans to ensure personnel safety.
- The liaison officer is the on-scene contact person for all additional agencies involved in the incident response.

In addition, each of these positions may have a number of subordinates, depending on the size and complexity of the incident.

By delegating the authority to make decisions regarding problems in these three specific areas of incident management, the IC's effectiveness can be improved.

When deciding to expand or contract the ICS organization, the IC should consider the following three major incident principles^{4,5,11}:

- Life safety
- Incident stability
- Property conservation

The first priority is always the safety of the public and all incident responders. Second, the IC must consider the stability of the incident when developing an efficient plan that maximizes the response effort and efficiently uses the resources available. Third, the IC is responsible for minimizing property damage while implementing the IAP.

After careful consideration of these principles and more, the complexity of the incident may cause the IC to activate any one or all additional general staff sections. Again, these include planning, operations, logistics, and finance/administration. Each section chief, in turn, can expand internally as needed. Finally, it should be reiterated that the complexity of the ICS organizational structure is dictated by the complexity of the incident—not the size, which is based on the geographical area or the number of resources involved.

FIGURE 30-1. Original ICS organization.

FIGURE 30-2. Command IC staff positions.

Planning Section

In small-scale incidents, the IC often assumes the responsibility of planning. However, when the complexity of the incident is of a larger scale, the planning section is activated by the IC. The planning section serves to continually evaluate the incident situation. Responsibilities of the planning section can be described by a number of functional units (Box 30-1).⁸⁻¹⁰

The situation unit collects incident information, processes it, and disseminates reports to all sections and agencies involved. The resources unit is responsible for accounting for all personnel and equipment, and the documentation unit maintains incident records. The damage assessment unit appraises property damages. A special needs population unit devises plans to protect those with special needs. A technical specialist and/or volunteers unit enables the response to access persons with specialized skills and knowledge related to the incident at hand. Finally, the demobilization unit organizes the de-escalation of all resources when an incident response comes to a close.

It should also be noted that a major responsibility of this particular general staff section is the creation of the IAP. The IAP defines incident response activities and which resources are to be used over a clearly specified period.^{1,4,8,10} Overall, the planning section has the critical task of anticipating the problems and needs of other ICS general sections and providing incident status updates to the IC.

Operations Section

The operations section is responsible for implementing the IAP developed by the planning section. The operations section chief has the primary responsibility of coordinating operations section activities in accordance with the IAP. Other responsibilities of the operations section chief include determining required resources and the organizational structure within the section, informing the IC of situation and resource status within the section, and assisting the IC in creating objectives for the incident.⁸⁻¹⁰

The responsibilities of the operations section as a whole take place on the actual scene of the incident. These activities include, but are not limited to, triage, rescue, emergency medical services (EMS), firefighting, and disaster relief services for victims (e.g., shelter).⁸⁻¹⁰ These branches, as they are called in ICS, may be broken down further into divisions or groups, as required by the complexity of the incident. The operations section chief decides whether the formation of these branches is necessary. It should also be noted that during an active response, the operations section is the only general staff section that has direct contact with the public. All other activities under the control of the remaining general staff sections are in support of the operations section.

Logistics Section

The logistics section functions to support all incident responders. This section is responsible for organizing the necessary facilities, personnel, and materials, including equipment, as determined by the operations section and requested through the IC. Like the planning section, the logistics section can be described by a number of functional units (Box 30-2).⁸⁻¹⁰

Remembering again that every general staff section can be expanded or contracted as needed, the logistics section can include a communications unit responsible for devising a communications plan and maintaining the lines of communications between ICS general staff sections and outside agencies. An information systems unit establishes and maintains the technology necessary to disseminate situation information to emergency workers. The medical unit in the logistics section provides care for incident responders, *not* civilian victims—civilian victims are cared for by EMS organized by the operations section. A food unit supplies food and water to emergency workers. A supply unit orders personnel and supplies for emergency workers. A donated goods unit manages the inventory of donated goods, which historically can be exceedingly large in disaster responses.¹² Finally, a facilities unit creates and maintains any necessary facilities used by emergency workers.

- Medical unit
- Food unit
- Supply unit
- Donated goods unit
- Facilities unit

Finance/Administration Section

Simply stated, the finance/administration section tracks incident costs. Careful records of all financial operations are necessary to ensure adequate reimbursement of costs. This is especially important when the incident is of such a large scale that a presidential declaration has been made. This general staff section has four key activities, which are assigned to functional units (Box 30-3).⁸⁻¹⁰

The time unit records all personnel time during a response. A procurement unit handles all contractual paperwork (e.g., for equipment). A compensation or claims unit handles injury and damage claims. A cost unit makes cost-saving recommendations. Of note, these activities usually occur within the EOC, which is discussed later in the chapter.

CONCEPT AND PRINCIPLES OF THE ICS

ICS concepts and principles have been time-tested and proven in all levels of governmental agencies and industry. To ensure that all persons who may become involved in an incident are familiar with ICS principles, ICS training is available.⁸⁻¹⁰ There are a number of core principles included in the ICS structure (Box 30-4).⁴

Common Terminology

Whenever an incident response involves more than one agency, common terminology within the emergency management system becomes a critical feature. Clearly, confusion and inefficiency can result when agencies have slightly different terms for major functions, facilities, personnel, equipment, and/or units. In ICS, terminology for all of these components has been pre-designated and standardized.^{4,8,10}

Infrequently, multiple incidents occur at the same time within a common jurisdiction. In such cases, the IC will assign his or her incident a unique name.⁵ This is particularly useful when a radio frequency must be shared for multiple incidents. In addition, inherent to this concept of common terminology is the guideline that plain English should be used in radio transmissions (i.e., without “ten” codes or agency-specific codes).

Modular Organization

The principle of modular organization is exemplified in Fig. 30-1. It develops as the first-arriving officer (who becomes the IC) assesses the complexity of the incident

BOX 30-3 FINANCE/ADMINISTRATION SECTION FUNCTIONAL UNITS

Modular organization
Integrated communications
Unity of command
Unified command structure
Consolidated IAP
Manageable span of control
Designated incident facilities
Resources management

and activates other functional areas as needed. For example, in ICS this means activating the planning section to assist in the creation of the IAP for a larger-scale incident.

Integrated Communications

Integrated communications refers to a system that establishes a single communications plan with a set of standard protocols that uses common terminology.^{4,8,10} The complexity of coordinating a hospital’s emergency response with the surrounding community illustrates the importance of a universally accepted communications system.

With regard to hospital and emergency department (ED) preparedness, internal and external communications are vital. Phone numbers for the Centers for Disease Control and Prevention, the Federal Bureau of Investigation, and the local public health department should be kept in the ED and laboratory.¹³ Unimpeded contact with agencies is important when reporting a possible bioterrorism attack, activating epidemiological surveillance, or requesting antibiotics or other supplies. Moreover, communications are needed to access assets such as Metropolitan Medical Response Teams, disaster medical assistance teams, and the National Guard Weapons of Mass Destruction-Civil Support Teams.¹⁴

Unity of Command

When attempting to establish a common set of incident strategies and tasks, it helps when multiple agencies and all personnel involved report to one designated person—the IC. This concept of unified command does *not* mean that any single agency gives up specific authority or accountability. All involved agencies contribute to the command process under the concept of unified command. Consequently, this allows the incident to function under a single IAP.^{4,8,10}

In addition, it is recommended that agency leaders regularly communicate before the onset of any large-scale emergency in an effort to get to know one another. Not surprisingly, such personal familiarity fosters cooperation among agencies that work together during any emergency response.

Consolidated Incident Action Plan

A complex incident response benefits from a consolidated IAP. By detailing operational objectives and support activities, order can be established amidst the chaos

that often surrounds complex incident responses.⁴ The IC decides whether a written IAP is necessary. At the minimum, ICS requires a written IAP whenever several agencies pool resources or multiple jurisdictions are involved. When written, an IAP may include a number of forms as attachments (e.g., traffic plan, safety plan, communications plan). Overall, a written plan is preferred over an oral plan because it protects against liability suits and provides necessary documentation when applying for state and federal assistance.^{8,10}

IAPs should be devised around a timeframe called an *operational period*. By using such operational periods, measurable goals are more easily achieved as response initiatives are focused for a shorter period, rather than over an undetermined length of time. Operational periods can be of various lengths but are usually no longer than 12 hours.^{8,10} The IC determines the length of the operational period after careful consideration of the incident complexity and size.

Manageable Span of Control

In ICS, manageable span of control is a concept that serves to control the number of resources that operate under an organizational structure to ensure efficiency. In particular, it demands that the number of individuals under one supervisor optimizes the effectiveness of the organization. Often the span of control of a supervisor averages five resources or individuals.^{4,8,10}

Designated Incident Facilities

At the minimum, there should be a designated facility where the IC, the command staff, and the general staff can collectively manage incident operations—the EOC.^{8,10} Staging areas are also required to prepare and organize all necessary resources before their deployment. Other facilities may be deemed necessary and can be assigned in a large variety of geographical locations.

The Emergency Operations Center

The EOC is where critical members of the ICS structure gather to collectively manage overall incident operations. Most jurisdictions maintain an EOC as part of their emergency preparedness program. During larger-scale incidents, the EOC may take on additional functions and will often extend its reach in several ways.⁵ For example, a forward command center may be established near the disaster area. In addition, a logistics center and/or EMS area can be established. However, with today's technology, the EOC itself can be located nearly anywhere.

Comprehensive Resources Management

The principle of comprehensive resources management serves to maximize resource use by consolidating control of resources. In doing this, there is more accountability, and freelancing is reduced.^{4,8,10} It is important to remember that personnel is a critical resource, and just like all resources, it can be assigned a status condition. For instance, “assigned” resources are active in an inci-

dent response, “available” resources are in the staging area awaiting assignment, and “out-of-service” resources are unavailable for assignment.

HOSPITAL EMERGENCY INCIDENT COMMAND SYSTEM

The HEICS is an emergency management system for hospitals and is made up of positions on an organizational chart (Fig. 30-3). Each position represented in Fig. 30-3 has a specific mission, and each position has an individual checklist designed to direct the assigned individual in emergency response tasks. These checklists are called *job action sheets*. In addition, the HEICS design includes standardized forms to simplify and enhance the overall system. Every job action sheet begins with the job title, the supervising officer, where the location of the section operations center is, and a mission statement to define the position responsibility.⁷

HEICS core attributes, some of which are based on basic ICS principles, include the following:

- HEICS provides a manageable scope of supervision for all personnel, similar to the ICS principle of manageable span of control.
- HEICS is a flexible system by virtue of its “modular organization”—another core ICS principle. It can be expanded or scaled back to meet the demands of a variety of crises, regardless of complexity.
- Job action sheets are position descriptions that have a prioritized list of emergency response tasks. They also serve to remind personnel of the standard established lines of reporting.⁷
- The job action sheets and the associated forms promote documentation of details and the overall response to the crisis. Such comprehensive documentation proves essential when trying to recuperate expenses and reduce liability.⁷

The HEICS organizational chart (see Fig. 30-3) imposes structure and understandable lines of authority within the hospital system. Just as in the original ICS, HEICS incorporates four sections of command under the overall leadership of an emergency incident commander. Each of the four sections—planning, operations, logistics, and finance—has a chief, appointed by the emergency incident commander, who is responsible for his or her section and the resources directly involved.*

SUMMARY

The ICS is capable of handling both small, routine operations and very large incidents that cover many square miles or involve multiple communities or states. Although many incidents will not require the activation of any of the four general staff sections, others will require some or all of the sections to be established.

*For more information about HEICS, contact the California Emergency Medical Services Authority at (916) 322-4336, or visit its Web site at <http://www.emsa.cahwnet.gov/>.

ICS is a simple yet detailed system. It is easily grasped but takes practice and familiarity to use it to its full potential. In an effort to promote and continually enhance the principles of ICS, training is offered through the FEMA, the Emergency Management Institute, and other like agencies. Through such courses or through independent study, one can achieve an understanding of the details of ICS and HEICS, which are far beyond the scope of this chapter. (For example, current ICS training and even hospital-based disaster plans such as HEICS now include standardized forms that simplify and enhance the implementation of these flexible systems.)

Scene Safety in Disaster Response

Robert L. Freitas

Emergency medical services (EMS) personnel receive training in scene operations and safety during the didactic portion of their training. The training covers the events and concerns in normal EMS response, such as motor vehicle accidents, acts of violence, and electrical hazards, to name a few. Despite this training, prehospital personnel are still injured or killed in the line of duty every year. A study in the *Annals of Emergency Medicine*¹ places the fatality rate of EMS workers at 12.7 fatalities per 100,000 workers compared with 5.0 fatalities per 100,000 workers for the general population. Because of poor data collection, less is known about EMS injury rates compared with those of other public safety personnel, although a study² by the Rand Corporation that examining injury rates for all public safety personnel does address the subject. In-hospital medical personnel are less likely to receive any training regarding scene safety for emergency medical response, although the emphasis on hazardous materials training for hospital personnel in recent years does provide some exposure to the concept.

Responding to a disaster presents a unique set of circumstances usually not found in the normal EMS response. Depending on the type of disaster, this could include secondary collapse of structures, operating in unfamiliar surroundings, exposure to smoke and dust, fatigue and dehydration, lack or disregard of safety equipment, and a host of other hazards. Ten emergency medical technicians (EMTs) and paramedics were killed at the 2001 World Trade Center (WTC) disaster, and at least 116 were injured.³ Both volunteer in-hospital personnel who respond to a disaster because of its proximity to a work site and EMS personnel called to respond to a disaster must be cognizant of the hazards and risks associated with such a response and be prepared to take measures to mitigate those risks. Responders who get injured or incapacitated add to the burden of other public safety personnel who must treat them as well as those injured in the original incident. Medical responders who get injured reduce available resources to the original victims.

HISTORICAL PERSPECTIVE

Healthcare personnel, both prehospital and hospital-based, have routinely responded to disasters with little

regard for their own safety. The body of literature on disaster medicine and management both in the United States and internationally is considerable, but little of this literature deals with the safety of emergency medical responders. Formal prehospital care has been evolving for four decades, with better training programs, teaching methods, and protocols; however, safety training and equipment for medical responders have lagged behind.

The formal Incident Command System (ICS), even though in use since the 1970s for some fire services, has only recently become a true component of health-care operations. EMS agencies have been slowly adopting the ICS during the last 10 years, and the hospital community is now implementing formal training, as mandated by the Joint Commission on Accreditation on Healthcare Organizations.⁴ Within the ICS and reporting directly to the incident commander is the incident safety officer (ISO), who has final authority over all operations in regard to responder safety. However, historically this organizational structure has not always been effective, especially when it comes to disasters. In large disasters, one safety officer often has not had enough resources to control the large number of responders, including volunteers, who arrive wholly unprepared for the tasks ahead. In the WTC terrorist attack of 2001, it was observed that “physicians dressed only in scrubs, clogs and surgical masks attempted to negotiate the jagged metal debris to carry out their well-meaning medical interventions.”⁵ In some situations, firefighters gave up their own personal protective equipment (PPE) to protect the volunteers.⁶

Many hospitals have had “crash boxes” of essential medical and surgical equipment for out-of-hospital response for years, but rarely has the equipment included safety gear. Clinical personnel from hospitals have routinely responded to disasters (and still do) with little or no safety training and even less PPE appropriate for the type of incident. In the 1995 bombing of the Murrah Federal Building in Oklahoma City, a volunteer nurse dressed only in jeans and a sweatshirt suffered a fatal head injury from falling debris.⁶ With the vast volume of literature that has come out after the WTC attacks, a true understanding of the problem of keeping responders safe has now come to light.

CURRENT PRACTICE

The current practice of scene safety for disaster response is still evolving, largely in response to review of the WTC disaster in 2001. The Rand Corporation, in concert with the National Institute for Occupational Safety and Health (NIOSH), has published a series of reports that attempts to broaden the knowledge base of this problem. Based on earlier research examining response to disasters, Rand and NIOSH undertook more research into the problem, publishing *Emergency Responder Injuries and Fatalities*,² which brings forth the discussion on understanding the types and causes of injuries to public safety personnel while also citing the current lack of adequate tracking methods for including EMS personnel in the data and offering suggestions on how to capture better data on EMS injuries and fatalities. Three other volumes look at the problems faced with protecting public safety personnel when they respond to disasters and offer solutions to better protect those personnel.⁷⁻⁹

Still, more effort needs to be expended in understanding how disaster response is different than situations normally encountered by both EMS and hospital personnel. Auf der Heide¹⁰ argues that the difference between the normal mission of emergency response and disaster response is not just one of magnitude managed by bringing into play larger numbers of people and equipment, but rather it is the interplay of a variety of factors. In normal response situations, responders might be exposed to a minimal number of hazards or risks, and usually for a very short period. In contrast, in disaster operations, responders may be exposed to multiple hazards and risks for prolonged periods and often without adequate rest (Box 31-1).

Large Geographical Scale and Unfamiliar Surroundings

In most emergency medical responses, activities are confined to a small area. Responders can readily identify hazards, see who else is responding, quickly estimate the extent of the emergency, and get a sense of how many victims there are. In disasters, especially natural disasters, the geographical scale of the disaster may be

overwhelming. The destruction from hurricane Andrew in Florida and Louisiana in 1992 covered more than 1000 square miles.⁹ In late 2004, a tsunami in southeast Asia spanned a vast area over three continents. Because of the possible large geographical scale and the loss of familiar surroundings that can occur during a disaster response, it may be difficult to request assistance if responders are not certain of their surroundings. They may be unable to see hazards that could affect them but are not in their immediate field of vision. The large geographical scale may also mean that responders are on-scene for many hours, days, or even weeks to ameliorate the effects.

It is reported that after the 2001 terrorist attacks in the United States at least “six federal and municipal fire and EMS departments, three private ambulance services and a number of volunteer fire departments and ambulance squads responded to the Pentagon” and that an ambulance as far away as Texas responded to the WTC disaster.^{3,6} Even though these efforts can be commended, responders unfamiliar with the local surroundings can present safety problems. Finding the way to a staging area or to the scene of a disaster will take more effort for personnel responding from long distances than it will for local units. Responders unfamiliar with the area can inadvertently end up in locations that might contain hazardous materials, as happened during the hurricane Andrew response.⁹ Even local responders can have difficulty navigating unfamiliar surroundings if local landmarks and signs have been destroyed, which also occurred during the hurricane Andrew response.⁹ Complicate this with the fact that during the initial stages of a disaster, the public may be evacuating the area, causing highway congestion that can contribute to motor vehicle accidents.¹¹ Responders unfamiliar with the area may not be aware of alternative routes to arrive at their assigned destination if roads are blocked or cannot be navigated due to damage or debris. Hospital personnel who respond to disaster sites are generally not familiar with operating in situations with little light, limited resources, and multiple hazards. Escape routes and safe areas may be difficult to find for those not accustomed to operating in a particular area. Electrical hazards, a problem even when responders are familiar with the area, become more of a problem in unfamiliar surroundings when responders who are trying to orient themselves might not be as vigilant as they normally would be and could walk or drive into hazards, such as live electrical wires. It is essential for responders to ensure that they know where they are going, how to find alternative routes if original routes are blocked, and how to contact coordinating agencies if they become lost. Global positioning systems, although not widely used in medical response, offer hope in allowing response units to navigate unfamiliar territory. It may be difficult to obtain maps in the early phases of a disaster, but having a map of the area is advisable, even if it is hand drawn.

Falling or Flying Debris

Debris from buildings, either damaged during the initial disaster impact or debris that is dislodged due to rescue operations, can be a problem. Medical personnel

BOX 31-1 RISKS AND HAZARDS ASSOCIATED WITH DISASTER RESPONSE

- Large geographical scale
- Unfamiliar environments and surroundings
- Falling debris
- Secondary collapse of damaged buildings
- Exposure to hazardous materials
- Excessive noise from machinery and equipment
- Adverse weather
- Inadequate PPE
- Debris fields, causing fall or trip hazards
- Convergent volunteers
- Secondary explosive devices planted by terrorists
- Prolonged duration, causing excessive fatigue, lack of sleep, and inadequate food and hydration

on-scene who are focused on treating patients may not be aware of hazards overhead, and noise from equipment operating at the site can mask the sound of the debris as it falls. Appropriate head and eye protection is critical for all personnel at the scene. The typical eye protection provided to healthcare workers for body fluid splashes offers little protection in a high dust or smoke environment, as was found during the WTC disaster; more than 1000 eye injuries were reported during the first 10 weeks of the WTC operations.⁷

Secondary Collapse of Damaged Buildings

Buildings that survive the initial shock in earthquakes can collapse due to aftershocks or from rescue efforts. WTC Building 7 did not collapse until after 5 PM on Sept. 11, almost 8 hours after the first plane struck one of the other buildings.⁶ Responders who plan to set up triage or treatment stations in buildings should first ensure that the buildings have been deemed safe by building engineers or ISOs and are at a safe enough distance from other damaged buildings in the event of collapse. Escape routes and safe zones should be determined while operating within the vicinity of damaged buildings.

Exposure to Hazardous Materials

There is always a risk of unintentional hazardous materials exposure at every disaster site. Intentional hazardous substance exposure through terrorism is covered in other chapters of this text, but hazardous materials are ubiquitous and can be found in hospitals, laboratories, railways, universities, and transportation centers, to name a few. During earthquakes, underground pipelines or above-ground storage tanks may be damaged, leaking hazardous materials into the environment.¹¹ Buildings damaged during explosions or earthquakes may have leaking fuel tanks, or chemicals used in manufacturing processes may be leaking or mixing together to form new, more toxic compounds.

Exposure to smoke, dust, and other airborne contaminants represents a major problem in disasters where there are large fires or when buildings collapse. NIOSH continues to study the effects of smoke and dust on rescue workers from the WTC attacks. It found that 60% of a subset (1138) of study participants who were evaluated from July 16 and Dec. 31, 2002, suffered from new-onset lower respiratory symptoms and 74% reported new-onset upper respiratory symptoms.¹² Proper PPE must be available and its use mandated on-scene by the ISO, and all disaster responders should have at least hazardous materials awareness training before venturing into disaster scenes. When in doubt about a situation, wait for special operations teams who have testing devices that can determine whether the scene is safe for operations.

Excessive Noise from Machinery and Equipment

Depending on the nature of the disaster, heavy equipment may need to be brought in to facilitate the response. This equipment may create excessive noise

either through the exhaust or from moving debris. This makes communication with other medical team members difficult and may make it difficult to hear warning signals indicating aftershocks, secondary explosions, etc. Although wearing hearing protection is advisable, it creates limitations similar to the original source of the noise. It is also usually designed for blocking high-frequency noises and not the low-frequency noises associated with heavy equipment.⁷ Additionally, it is difficult to hear radios and other communications devices while wearing the protectors.

Adverse Weather

Because healthcare workers generally dress for their immediate shift, they may be unprepared to deal with the prolonged nature of disasters. EMS workers accustomed to short-sleeve uniform shirts for daytime wear in the summer might find themselves getting chilled by evening, and hospital personnel who respond in hospital garb might be unprepared for sudden rainstorms. Responders to the Oklahoma City bombing had to deal with temperatures that fluctuated from 80° to 40°F, strong winds, rain, and lightning.¹³ Healthcare workers both in and out of the hospital who might be called on to respond to disasters should have clothing appropriate for a wide range of weather conditions, including cold weather gear and rain gear.

Inadequate Personal Protective Equipment

EMS and hospital workers are commonly not well prepared and inadequately trained for disaster response when it comes to PPE. Administrators' budgets are often thought to be too lean to spend money on something that happens infrequently and requires a large outlay of funds and training time.⁸ It is also suggested that because there is no central federal authority responsible for monitoring PPE for medical response personnel, unlike firefighters and the National Fire Protection Agency (NFPA), funding from government sources for PPE is reduced.⁸ Even NFPA's *Standard on Protective Clothing for Emergency Medical Operations*¹⁴ only deals with exposures from body fluids and not the types of hazards likely encountered in disaster operations. Experiences from recent disasters indicate that even with good PPE, the multihazard nature of disasters makes it difficult to have the right equipment all of the time.⁷ In a disaster environment, PPE must not only protect the wearer from bloodborne pathogens but also offer protection from other disaster-specific hazards. In addition, due to the extended nature of disaster response, agencies must be able to replenish PPE as it wears out, becomes wet, or breaks down from exposure to chemicals. The multiagency response aspect of disasters can also make the sharing of equipment difficult. With multiple standards for PPE across public safety entities, the chance of cross-agency compatibility of PPE is small. PPE that might be adequate for firefighting is generally not acceptable for the treatment phase of patient care, although it might be appropriate for the patient access

phase. Having access to bunker gear is not the answer either, as experiences have indicated that too often bunker gear is too heavy and cumbersome for the prolonged response required to deal with disasters.

Eyewear designed to prevent exposure to body fluids is not adequate for removing patients from rubble piles in high dust environments. Face shields or glasses designed to offer splash protection may not be appropriate in situations in which dust or smoke can penetrate the sides of the glasses/shields. Safety goggles of the kind used in construction may be more appropriate, although they may be uncomfortable for prolonged periods, may fog, and can hinder peripheral vision.⁷ Resources should be available for rinsing off glasses because dust and dirt particles can lead to scratched lenses, hindering visibility. Many medical responders are not issued hand protection that complies with Occupational Safety and Health Administration standards for protection from “absorption of harmful substances; severe cuts or lacerations; severe abrasions; punctures, chemical burns; and harmful temperature extremes.”¹⁵ Gloves designed to protect against bloodborne pathogens, even though appropriate for general patient care, should be worn underneath a more durable glove when operating in the multihazard environment often encountered in disaster situations; leather is not advised because it absorbs water and cannot be decontaminated. A glove that resists wear, cuts, and punctures but is pliable enough to provide treatment is necessary.

Relying on other agencies or resources to provide adequate equipment is not advised. The different agencies responding to disasters use a variety of brands and models of equipment, making compatibility with respirators, face masks, and cartridge filters not guaranteed. Responders should not use equipment offered by others without at least some training in its use (Box 31-2).

Debris Fields, Causing Fall or Trip Hazards

Most disasters, with the exception of chemical and biological exposures, will cause debris, often over large

BOX 31-2 LEVEL D PPE FOR DISASTER RESPONSE UNDER HAZARDOUS CONDITIONS*

- Long-sleeve shirts
- Protective head gear to protect against falling debris or walking into objects
- Waterproof boots when there is the potential of rolling or falling objects or objects piercing the sole (steel toe boots may cause blistering after prolonged wear)
- Gloves that protect responders' hands from absorption of harmful substances, cuts, lacerations and punctures, and burns
- Eyewear with detachable side protection when there is exposure to dust or other harmful particles
- Battery-operated or rechargeable hand light if the charging unit is with the responder
- Foul weather gear
- Cold weather gear

* Not indicated for response to chemical, nuclear, biological, or radioactive incidents

areas. Hurricanes may leave huge debris fields. Hurricane Andrew destroyed or damaged more than 130,000 homes, including 90% of all the mobile homes in Miami-Dade County.¹⁶ This caused a huge debris field that had to be carefully negotiated by rescue workers. In the aftermath of the Murrah Building bombing, debris was piled 35 feet deep.⁹ Debris may consist of wiring, pipes, pieces of concrete, and other building materials; is sharp; and may wear down protective clothing. The southeast Asia tsunami left debris fields kilometers deep along the coastline of the vast area it affected. Debris may need to be cleared to gain access to patients or set up treatment areas. Wind may cause debris to be blown about long after the initial disaster. Being on the lookout for responding apparatus or overhead hazards may cause responders to not look where they are going, resulting in injuries from trips and falls. It is imperative for responders to have a good light at all times, even if the initial response is during the day. Trying to navigate through debris after dark is a perilous operation, even with a light. Furthermore, it may be necessary to enter buildings that have lost power during the day. The penlights used in hospitals are not adequate for this purpose. Lights with disposable batteries or those that can be recharged if the responder has the charging device on hand are recommended. Units without rechargers will only be useful as long as they can be charged. The prolonged nature of disasters may preclude the responder from having the ability to retrieve the charging device.

Convergent Volunteers

Part of the healthcare ethos is the spirit of volunteerism. This is especially true in disasters. Responders want to help those in need, whether this is done in an organized fashion through disaster medical assistance teams (DMATs) or Salvation Army or Red Cross volunteers or through individuals who respond to the scene, often without any training or equipment. Responding agencies may have different protocols, equipment, and staffing configurations. Most of the official volunteer agencies at a disaster scene will be there due to a request for a response. Even though they may present logistical challenges, most usually do not present safety challenges. Failure to communicate between those on official response to the scene and those freelancing causes a breakdown in the ICS and may cause resources to be used in a haphazard manner, potentially endangering responders. Freelancers generally will not have radio communications with command centers or other responders, causing inadequate resource utilization. The response to an airliner crash in 1988 at the Dallas-Fort Worth airport demonstrated this point. Freelancing response units unfamiliar with the airport disaster plan set up a triage site outside the airport, causing responders to continue to look for patients and victims at the crash site who had already been evacuated.⁶ Accountability for the safety of all on-scene also suffers when ISOs are unaware of all personnel operating on the scene. Accounting for all responders on-scene is also important in the event of postincident monitoring for hazardous exposures, as in the WTC disaster. There is evidence to

suggest that most of the convergent volunteer organizations that respond as freelancers come without proper equipment, either pulling equipment out of the hospital that might be needed there or using equipment from other responders on-scene, neither of which is an optimal situation.⁶ Volunteers cannot always be counted on for completing tasks, especially if they have not received proper training on how to do the task and are unfamiliar with terminology used by other responders.¹⁰ Directions to volunteers should always be clear and easy to understand. In addition, the person issuing the directions should be certain the volunteer understands the task. For in-hospital personnel interested in responding to disasters outside the hospital, joining a professional group within a disaster section or other volunteer disaster medical organizations, such as the National Disaster Medical Service, is beneficial.¹⁷ These organizations provide training and decrease the chance that volunteer responders will arrive unprepared, creating liability for others. Because volunteers at disasters are a fact of life, coordinating agencies should develop clear strategies for dealing with them and for integrating them into the response, delegating an individual in advance to have responsibility for managing the volunteers.¹⁰

Secondary Explosive Devices Planted by Terrorists

Every disaster or incident as a result of terrorism has the risk of secondary devices that can cause injury to medical personnel already on-scene. Two Atlanta area bombings in 1997, though not classified as disasters, are noteworthy for having secondary explosive devices: one at a family planning center where the secondary device exploded 1 hour after the first device exploded, injuring four public safety personnel from shrapnel and blast effects, and another at a lounge where the secondary device failed to explode (if it had, it would have injured responders in the vicinity).¹⁸ In the WTC attacks, the second plane struck the south tower approximately 15 minutes after the north tower had been struck by the first plane; many responders were already on-scene by the time second plane struck.⁷ Responders must always exercise caution for secondary devices in terrorism attacks, being on the lookout for strange packages or people in the disaster area who clearly have no readily identifiable purpose there. A plan for retreat or an understanding where safe zones are is essential during operations.

Prolonged Duration, Causing Excessive Fatigue, Lack of Sleep, and Inadequate Food and Hydration

Because of the long-term nature of disaster response, it is easy to get fatigued, not get adequate sleep, and not take the time to eat or drink appropriate amounts of fluids. Responders at Oklahoma City reported working shifts longer than 24 hours, with a deleterious effect on their scene awareness and judgment.¹⁹ The Rand research indicates that responders have a tendency to do what their leaders do, and if the leaders do not take adequate

time for rest and rehabilitation, neither will their subordinates.⁹ Disasters commonly require calling in off-duty personnel to take over operations when initial responders become fatigued.¹⁰ It is recommended that all responders, including senior personnel, work no more than one 12-hour shift daily.¹⁹ This may need to be adjusted down, depending on the working conditions. Having adequate food and drink nearby that are consistent with one's personal dietary habits is also important.

SCENE SAFETY AT THE DISASTER SITE

According to Garrison, "Avoiding danger is counterintuitive to rescuers."²⁰ Eliminating all hazards and risks associated with disaster medical response is impossible, and most EMS personnel know the job is dangerous at times. As can be seen in Table 31-1, disasters are complex situations, and every one is different. Therefore, the challenge in disaster response is to manage the risks by having an appropriate mechanism for understanding the dynamic nature of disaster operations. Managing risks is best done by using the safety management cycle (Fig. 31-1). It involves three functions that must be performed continuously throughout the incident: (1) gather information about the current situation, (2) analyze the available options and come up with decisions, and (3) implement decisions.⁹ Gathering information at disaster sites is a challenge. The sharing of information across agencies is key to protecting those on-scene. The number of organizations responding to disasters, especially those caused by terrorism, is enormous, with one report citing 159 public-sector agencies responding to the Sept. 11, 2001, WTC disaster and another 290 organizations involved in the response.²¹ Many of the different agencies involved in a typical response focus solely on their own organizational tasks and do not see how their activities fit into the big picture. Auf der

FIGURE 31-1. Safety management cycle. (Redrawn from Jackson B, Baker J, Ridgely M, et al. *Protecting Emergency Responders, Volume 3: Safety Management in Disaster and Terrorism Response*. Santa Monica, CA: The Rand Corporation, Science and Technology Policy Institute [for the National Institute for Occupational Safety and Health]; 2004.)

Heide¹⁰ describes this as the “Robinson Crusoe syndrome,” causing responders to believe “we’re the only ones on the island.” Many of these agencies may possess needed information on the hazards already encountered and hazards already mitigated, may have special expertise in disaster activities or risk assessment, and may possess information on the locations of victims, or resources needed by other groups, etc. Use of the ICS, covered in Chapter 30, is essential. It is this author’s belief that in disaster activities, there is no single activity that can have a greater impact on scene safety than a properly functioning ICS, in which all agencies share information. Of equal importance, the incident commander must share all the appropriate information with those on-scene.

Because of the large geographical scale of many disasters, the ISO may not have an accurate picture of all the hazards present, especially if there is limited communication between all of the responding agencies, a common problem in most disaster situations. Medical organizations that routinely respond to disasters are encouraged to have their own safety officers or have one of their members appointed as an assistant ISO, with communications channels to the ISO. Using the NFPA’s *Standard for Fire Department Safety Officer*²² as a guideline, the role of the safety officer is to determine when activities are unsafe or involve significant hazards and then exercise the authority to immediately “alter, suspend, or terminate those activities.” When the ISO determines that hazards or activities do not represent an immediate danger, the ISO “takes appropriate action through the incident commander to mitigate or eliminate the hazards.”

Once the information has been gathered, the next step is to look at the options available and make a decision, taking into account as many variables as are known. For example, in the initial response of medical personnel to the scene of a disaster, patients requiring rescue may be present. Many victims may also present either self-rescued or rescued by other victims, requiring treatment. Taking the time to analyze the options may make responders realize that there are trained search and rescue personnel nearby and the available resources may be better used in setting up a treatment site first and leaving the rescue to personnel appropriately trained and equipped for the task. Once the decision is made, the next task is to follow through on the decision by taking action. The decision for any action related to safety must be communicated to all those within the immediate span of control and also up the chain of command to the incident commander. It is of great importance to know who is on-scene and how to communicate to them. As happens in many disasters, off-duty personnel will respond from home and therefore may not have adequate communications equipment (e.g., portable radios, pagers). Knowing where they are at a given moment may be a difficult task. If electronic communications are not possible, the use of runners is always an option and is often a good use of volunteers if communications to them are clear and concise.

Crew Resource Management for Safety

If a decision is made regarding safety, there must be an understanding in advance that good safety practices are

not optional and that the action to be taken is mandatory for all within the scope of the organization. The ISO might ultimately make a safety decision, but reasonable input and discussion should take place with those involved on-scene. Crew resource management (CRM) for safety practices has been in existence for approximately 25 years. Originally called *cockpit resource management*, it came out of an examination by NASA of air crashes and the role that human error played in them. It has since been adopted for use in medicine, both in the training of emergency department, labor and delivery, and operating room staffs and air-medical operations.²³ The primary tenets of the training are to discuss how errors are caused and how operating in high-stress environments with high workloads, fatigue, and dealing with emergency situations contributes to errors. The principles of the training include seeking information by asking questions, advocating positions, communicating actions, and discussing and resolving conflicts. CRM is not something taught en route to or on-scene at a disaster; it is put into place during the preplanning and preparations phases of the disaster and may present a challenge to the medical community if not discussed in advance. For example, the medical director of an EMS agency must understand that a decision regarding safety applies to him or her as well, even if the decision is made by a safety officer who is a basic EMT. Obviously, safety concerns or mandates must be reasonable for the current conditions; mandating the wearing of safety helmets in a treatment center remote from where there is little risk of falling debris would not make much sense. The same mandate in an active incident area, where there is a chance of falling debris and therefore not allowing clinicians without adequate head protection to enter, would clearly be within the bounds of the safety officer. CRM also teaches that the same medical director just described should feel comfortable telling the ISO that he or she has noticed a crack in the building foundation and inquiring without risk of being ostracized whether it is safe for the treatment team to be there. As has been stressed here, disaster operations are not a static event; the hazards present 8 hours ago may have been dealt with or were determined to be unfounded, but those responsible for safety must constantly reassess the situation and gather new information, analyze the current options, and make new decisions, all of which may result in taking new actions. This safety management cycle must be repeated throughout the event until the incident is considered closed. Good preplanning and preparations before the actual response, with training that includes scene safety procedures, will reduce injuries.

Response to Disasters

Initial notification of a disaster may come in many ways—some informal, others formal. Hospitals may become aware of a disaster when the first patients arrive at the ED door. Public safety agencies may find out through a flood of phone calls to the public safety answering point (PSAP) or if the disaster directly affects the building they are located, such as if the dispatch building trembles from an earthquake. For many, the ini-

tial notification may be through media outlets; others will be directed to the scene via official dispatch. Once the decision is made that a response to the disaster is indicated, based on an official request of some sort for assistance, the first thoughts of the medical responder should be personal safety, and this should generate some questions:

- *What PPE will I likely need, and if I don't have it, where will I get it?* Expecting others to provide adequate PPE once you arrive on-scene, unless this has been prearranged, is a dangerous thought. The PPE that awaits you may be equipment you are unfamiliar with or the wrong size. At a minimum, responders should be equipped with appropriate Level D gear, including a safety helmet, adequate footwear, easily visible identification (e.g., reflective vests with skill level clearly stated on it), safety gloves, eye protection, a hand light, and equipment for bodily substance isolation precautions.
- *What hazards are likely to be present based on the location?* If responding to an industrial site, the presence of hazardous materials must always be suspected and different PPE or a different approach to the scene might be needed. If responding to an explosion, the concern over terrorism or secondary explosions must always be considered. Responses near water might require the use of personal flotation devices for responders. Practice an all-hazards approach with the expectation that there will be hazards on-scene, and be prepared to mitigate them.
- *Where am I going, and how do I get there?* If the incident is very large, such as Hurricane Andrew was, responders may be called in from great distances. On occasion, specialized resources (e.g., a surgical team) may get an escort directly to the scene. Badly needed specialized resources do not want to spend hours lost looking for an appropriate rendezvous point or the active incident, and the people on-scene may not have the time to wait. Know where you are going; if you do not, request an escort. Have maps, but keep in mind that local landmarks may have been destroyed. Take the time to download directions from an online map service; it is better to take 5 minutes to get detailed directions than to spend 1 hour trying to find the final destination.
- *Who will I report to when I get there?* If the ICS has not been established yet, then it may be more important to understand that as the first arriving unit, you will be expected to size up the scene and report the situation to the communications center instead of providing treatment to the first patients encountered. If the ICS has been set up, it is important to know who you are reporting to, where to find them, and let them know you have arrived. Updates on your situation are recommended every 30 minutes, unless other rules are in effect.

Scene Size-Up

Once the actual response is under way and regardless of whether response time is expected to be 30 minutes or 30

hours, try to get an update, if possible, of the current conditions on-scene. As responders approach the scene, they should begin determining the scope of the situation and continue to do so until preparing to depart the scene after disaster operations are completed. In the initial early minutes of the response, communications center personnel may be too busy receiving calls and dispatching units to be of much help, but even information being relayed to other units may be useful (e.g., traffic congestion or the presence of hazards). Responders must be vigilant for bystanders and victims fleeing the scene or curious onlookers running toward it. Once near the scene, responders must look and listen for other emergency responders because some who are heading to the scene may be unaware of your presence or where they are going. Responders should look for signs of power outages, which could indicate downed power lines, and look for smoke or fumes.^{24,26} If being transported to the scene by someone from another agency, the responder should not assume that the person operating the vehicles has more knowledge about scene safety than himself or herself; throughout disaster operations, one must take responsibility for one's own safety.

As the responder gets closer to the scene, the presence of odors may indicate chemicals, fire, or other hazardous materials. One must quickly make an assessment whether hazardous materials are evident and if they pose a direct hazard, either as a by-product or the direct cause of the disaster, so that the responder does not end up as a victim.²⁶ The U.S. Department of Transportation's *2000 Emergency Response Guidebook*²⁵ is a very good field resource for responders who believe there is a danger of hazardous materials present.

As discussed, downed power lines are a common and deadly hazard. If the power is out and you observe damaged poles, count the number of wires at the damaged poles and then at the next undamaged pole down the line. If the number of lines atop the damaged pole is the same, there is a good chance the lines are intact.²⁵ On arrival at the actual disaster scene, even before the vehicle comes to a stop, a decision will need to be made about where to park the vehicle. Vehicles should park upwind and uphill if possible to avoid toxic fumes or smoke. Scanning for the direction that flags or smoke are blowing may be good indicators of wind direction. Typically, emergency vehicles will try to get as close to the area as possible. Events at the WTC indicate that this may not be the wisest approach. One witness reported seeing a row of 15 ambulances, stating, "They were crushed, completely gutted by falling debris."³ If a vehicle is not likely to be needed for emergency transport of patients and if it does not have needed supplies, PPE, or communications equipment, it should be relocated to another location safely away from the scene. If it does have needed equipment, consider offloading the equipment and having the vehicle relocate to a safe location. Other vehicles may also be vying for the same space you are occupying and may be more urgently needed; an example would be an aerial ladder truck for rescue efforts. If there are burning vehicles, response units should park no closer than 100 feet from any of them to minimize explosion hazards or the risk of being exposed to leaking fuel.²⁶

Lookouts, Communications, Escape Routes, Safety Zones

Wildland firefighters and urban search and rescue technicians use an easy-to-remember system that can be adapted for disaster operations, known as LCES (lookouts, communications, escape routes, and safety zones).^{11,27} Being a lookout is normally the function of the ISO, but due to the scope of a disaster, the ISO may not be in proximity to all operations or not all responders may have communications with the ISO. In the event there are hazards present, it is important to have an individual who has good visual access to the operations and is not involved in patient care as a lookout, or site-specific safety officer. This person should be free to watch over the operation; identify hazards or potential hazards; and if appropriate, mitigate them. He or she must be readily identified, either by his or her location or by wearing a vest identifying him or her as a lookout or safety officer.

Communications should be established on arrival, not only with the incident commander but also with dispatch centers. On arrival, an exact location should be established for responding teams. This may be difficult if street signs have been destroyed, but it is imperative for all assets to have known locations. Using easily identifiable landmarks, such as buildings in the area, can be of assistance. For example, stating “we are on the south side of the lake” is not an exact location, but it can be useful. Global positioning system devices can be of great assistance in establishing location.

Radios may not be functioning, may be overloaded with emergency traffic, or may not have common frequencies, and the use of runners may be necessary. The lookout or communications person should be alert for other forms of communications that may be used at disaster sites. Search and rescue technicians use an emergency alerting system that consists of an air horn or siren to be used in the event of emergencies:

- Three short blasts of one second each is an indication to evacuate.
- One long, 3-second blast means to cease operations or work noiselessly.
- One long blast and one short blast means to resume operations.

Depending on the nature of the disaster, it may be important to determine escape routes in advance of needing them. During rescue operations at the Oklahoma City bombing, there were three bomb scares, causing evacuation of the treatment areas.¹³ Personnel or vehicles may become trapped in a location by other responders and may need to relocate. On occasion, the shortest route to safety may not be the most direct, as in the case of a building collapse in which the shortest route to safety may direct one into the collapse zone. Clearly in this event a more circuitous route may be the safest.

The establishment of safe zones may be important in disasters where the risk of ongoing hazards is great. The safe zone is an area determined to be relatively safe from hazards and might be an area removed from collapsed or damaged buildings, an area remote from hot or warm

zones in hazardous materials incidents, or an area where additional measures have been taken to increase building structural integrity. If team members are evacuated to the safe zone, a head count should be the first task done when members arrive to ensure that all members are accounted for.

PITFALLS

A lot has been learned about responder safety since Sept. 11, 2001. The Rand/NIOSH collaboration has brought great resources to emergency managers for keeping all responders safer.^{2,7-9} Measures are being put into place to keep better data about medical responder injuries at all incidents, but there are still pitfalls in all of this. Disaster medical services are provided by many organizations, with different standards. The federal government should determine a standard of safety for emergency medical response, as has been done with firefighting through the NFPA. Research is essential; journal articles and educational materials help keep the subject in the spotlight. The Rand studies illustrate the problem with designing PPE that allows medical responders to do their jobs safely. Complacency is the major pitfall to all of this, and if it does not turn into action, medical responders will still face injury or death while responding to disasters. Standards, PPE, and training must be implemented while disasters such as the WTC and the south-east Asia tsunami are still fresh in our minds.

Needs Assessment

Shan W. Liu

Development of the field of needs assessment, or rapid surveillance, has been critical to improving the efficiency and effectiveness of public health interventions. Needs assessments have served organizations on all levels—local, state, and federal—as the essential foundation for policy and program development and resource allocation. In fact, needs assessment, along with policy development and assurance, is one of the core functions of public health.¹

Disaster medicine is no different in terms of the critical role that needs assessment plays in maximizing appropriate response. In sudden-impact disasters, the most effective efforts to minimize mortality are based on very specific, precisely targeted interventions against demonstrated causes of death.^{2,3} Too often, relief responses are based on intuition rather than data. Disaster needs assessments can be used to understand the impact of disasters on public health and the infrastructure of the medical system, enabling the relief community to respond much more effectively. The purpose of a needs assessment is to rapidly survey a postdisaster situation, provide data describing the magnitude of the extent of the emergency, and alert the relief community so that appropriate interventions can be mobilized and certain assets brought to the scene. In essence, it attempts to bring order to the chaos that results from a disaster.² By necessity, needs assessments must be performed even as emergency services are being provided.⁴ These assessments provide a medium for advocacy that ensures that the response to a disaster is not just what pleases donor political constituents, but addresses the real problems of the affected community.⁵ It is the goal of this chapter to introduce the main components of and rationale behind disaster rapid needs assessment.

HISTORICAL PERSPECTIVE

Historically, the perception has been that charity manages relief efforts, in which groups or individuals provide supplies and efforts, regardless of the needs of the situation. Consequentially, the health response to emergencies in the past usually was ad hoc, inappropriate, and inefficient.⁶

The introduction of disaster needs assessments may have started with the practical application of epidemiology during the massive international relief operations in

response to the Nigerian civil war in the 1960s. Centers for Disease Control and Prevention epidemiologists developed new techniques for the rapid assessment of nutritional states as well as for conducting surveys. However, widespread implementation of such techniques lagged behind in disaster relief efforts. By the 1970s, the need for disaster epidemiology was evident. Directors of major relief efforts doubled as managers and planners and often lacked sufficient public health experience to successfully respond to major catastrophes. Disaster scenes continued to be cluttered by outdated, unlabeled, and inappropriate medications.

The 1980 Mount St. Helens' disaster served as a historical milestone in terms of shaping the way the federal government responds to disasters, particularly regarding coordination between multiple levels of government agencies. Epidemiological research subsequently became central to targeting strategies according to the needs of the disaster, leading to more appropriate responses and resulting in decreased mortality and morbidity from disasters. By the late 1980s and into the 1990s, interest in the public health of disasters accelerated, notably with the emergence of new professional societies and scientific forums.⁷

CURRENT PRACTICE

Although each particular disaster merits a specific needs assessment, the World Health Organization (WHO) has designed rapid health assessment protocols for common emergencies. In general, the major steps of a rapid health assessment include description of purpose, preparedness, planning, conducting the assessment, analysis of data, and presentation of results.⁸ The main priorities are to determine the location of the problem, the magnitude of the crisis, and the immediate priorities.²

Before addressing the many steps involved in conducting a needs assessment, two major questions to be asked and answered are: Who performs the needs assessment, and who receives the reports? Ideally, such a project would be performed by an agency that will ultimately implement the relief program. A team should consist of interdisciplinary staff trained in collection of accurate and precise data, such as an epidemiologist, statistician, engineer, and health planner. Such a team should

also have members from the host country and/or community as well as from local nongovernment groups, as deemed appropriate.⁹

A critical aspect of performing a needs assessment is directing the report to the appropriate audience. The main recipient will, of course, be the agency that sponsors the survey. However, it is imperative to keep in mind that such information should be dispersed as widely as possible. Hence, the audience will undoubtedly include survivors, nongovernment organizations (NGO), United Nations agencies, donor governments, and media representatives. Each group will have varying roles and consequentially differing informational needs.

Purpose

In disasters, the rapid assessment entails collecting subjective and objective data that measure damage and identify the critical needs of the affected community to design appropriate, immediate response priorities. By virtue of being a rapid assessment, it must be performed in a limited amount of time, either during or immediately after the emergency phase. Ongoing assessments will need to be performed during the rehabilitation and recovery phases of the disaster.²

The major parts of a needs assessment are as follows^{8,9}:

- Confirm emergency
- Describe type, impact, possible evolution of disaster
- Alert international community to gravity of situation
- Measure present and potential health impact
- Assess adequacy of current response capacity and immediate needs
- Recommend immediate response

Being mindful of the main parts of needs assessments will help focus efforts and preparedness.

Preparedness

Though impossible to plan for all potential disasters, it is imperative that health systems have at least basic infrastructures in place to be able to immediately implement an appropriate rapid assessment and response. Disaster preparedness includes the following:

- Training and evaluation
- Monitoring
- Emergency planning
- Vulnerability assessment

Most of the preparation entails anticipation of needs and organizing a response system that can be quickly deployed when emergencies arise. According to WHO rapid health assessment protocols, emergency preparedness ought to include the following questions:

- Does a national health policy exist regarding emergency preparedness, response, and recovery?
- Who is the person within the ministry of health in charge of emergency preparedness?
- What type of coordination exists between the health sector, civil defense, and other key government ministries?

- What type of coordination exists between ministries of health, the United Nations, and NGOs?
- What operational plans exist for disasters?
- Do national and local health plans exist for disaster management?
- Are surveillance measures in place that can detect early signs of disasters?
- Have environmental health services taken preparedness steps?
- Have facilities and areas been identified to serve as shelter sites?
- What training activities exist for disaster preparedness? Who is involved? Have disaster drills been administered?
- What resources exist to facilitate rapid response to disaster (e.g., emergency budget, supplies)?
- Does a system exist for updating information on key human and material resources needed in a disaster?

Even though each disaster situation requires its own rapid needs assessment, the most effective disaster efforts begin with proper preparedness and planning, long before any disaster occurs.⁸

Planning

On hearing reports or even rumors of a disaster, the preparedness checklist should be updated. However, different types of disasters will require varying timeframes for response. Rapid-onset emergencies (e.g., earthquakes) require immediate assessment within hours of the event. On the other hand, assessment in floods and population displacement emergencies can be done within 2 to 4 days.

With disaster emergencies, there are generally four main stages included in the planning of rapid needs assessment:

- *Stage I (day 1)*: Generally when the local community responds to the crisis with little to no information. Initial injury and death estimates are necessary within 24 hours, as a preliminary guide to which resources will be needed.
- *Stage II (day 2)*: Largely entails focusing the rapid assessment on resources needed in less accessible areas; shortages in primary healthcare resources; and secondary needs, such as shelter, food, and water. It is at this time that needs for additional aid, such as national or international assistance, should be assessed.
- *Stage III (days 3-5)*: Securing shelter and restoring primary healthcare become essential. As such, the assessment focuses more on environmental health, food, special protection, and the restoration of primary health facilities for vulnerable groups.
- *Stage IV (after day 5)*: By this time, disaster responses should be fully implemented. The assessment at this point should be focused on establishing a surveillance system and analyzing health trends.

Final preparation includes deciding what information to gather, coordinating different organizations, selecting team members and leaders, and delegating administrative

assignments. Team members should include those with familiarity of the region and population affected, experience with the type of emergency, epidemiological analytical skills, and the capacity to make decisions with sparse data. Logistics, such as travel clearance, transportation, safety protocols, and developing communications systems, must also be addressed before conducting the assessment.

Conducting the Assessment

The specific information gathered during the immediate emergency phase of the disaster should include the following²:

- Establishing the boundaries of the affected area.
- Identifying transportation issues on main routes to affected areas.
- Identifying major threats to survivors (e.g., landslides, damage to chemical plants).
- Determining damage to broadcasting facilities.
- Determining needs for establishing/restoring communications between major responders.
- Assigning surveyors first to areas where there have been no reports received.
- Assessing the status of hospitals—specifically regarding access to affected areas, damage to hospital structures, operational capability, and availability of personnel and essential equipment.
- Beginning to survey isolated and severely affected communities and assess adequacy of treatment of injured people in those areas.
- Prioritizing areas that need organized search and rescue efforts.
- Assessing level of damage to air-traffic centers—runways, fuel storage, etc.
- Reviewing government stockpiles of accessible essential items.
- Assessing integrity of lifeline services in order of priority: communications, water supply, electric power, road networks, and sewage system.

Rapid surveillances must be systematic and neutral.⁵ Despite having to conduct an assessment during the chaos of a disaster, it is imperative that data collection and analysis be performed in a standardized fashion. The four main types of information collection methods are: (1) review of existing data, (2) inspection of affected area, (3) key informant interviews, and (4) rapid surveys. When reviewing existing data, government and international and national NGOs may be sources of information regarding the geographical characteristics of the area, the size and prior health status of the community, and the existing health services. They can also serve as resources for an emergency response operation.

Inspection of the area can be accomplished by air and/or on the ground. Aerial assessments are most helpful in determining the extent of the area affected and conditions of the infrastructure and environment. Group assessments will provide a better sense of shelter and food availability, potential hazards, and a gross sense of the size and type of population affected. Whether by air or ground, observations from the initial inspection

should be used to create maps that include the area affected and location of pertinent resources, such as health facilities, water sources, shelter, and food distribution sites.⁸ Another vital aspect of aerial inspection is to estimate a reliable denominator. Since rates depend on a somewhat accurate estimate of the population at risk, estimates of population counts (i.e., house counts multiplied by average family size) can be used as an initial estimate of the denominator.⁶

Key informant interviews should be conducted from each sector of the affected community and are central to the assessment. These interviews will include community leaders, local government officials, health workers, and personnel from other emergency response groups. The information from these informants should include the following:

- Subject's perception of the event
- Previous condition of the area
- Size of the affected community
- Adequacy of security, prevalence of violence
- Estimated morbidity and mortality rates
- Existing food supplies and needs (e.g., approximately 1900 to 2100 kcal/person/day)
- Supply and quality of water (e.g., generally 15 L clean water/person/day)
- Adequacy of sanitation (e.g., 1 latrine per 20 persons)
- Existing fuel and communications lines
- Existing resources in community

Although key informant interviews can rapidly provide information, surveyors should always keep in mind that such data are likely to be exaggerated.^{8,9}

Aside from inspection of the area and key informant interviews, surveys are central to accurate situational assessments. However, although rapid surveys are likely to be less biased, they take more time and resources. Hence, surveys should be conducted when the information cannot be reliably obtained from other sources. Some of the more common methods of rapid surveillance during disasters are the following: sentinel surveillance, sampling methods, and detailed critical sector assessments.

Sentinel Surveillance

This method is largely used when professional staff create a reporting system that detects early signs of particular problems at certain sites. This is particularly useful during the early warning phase.

Surveys by Specialist Teams (Sampling Methods)

Well-designed surveys from reliable samples allow researchers to confidently generalize findings and apply them to a larger population. There are multiple methods for sampling:

- *Simple random sampling*: When every member of the population at risk is equally likely to be selected and such selection has no effect on other selections.
- *Systematic random sampling*: Choosing every 20th subject, for example, on a list. This is potentially inaccurate if the list is nonrandom or incomplete.

- *Stratified random sampling*: Divide the population into strata, randomly select subjects, and then combine them to give an overall sample.
- *Cluster sampling*: Samples are restricted to a limited number of geographical areas, called clusters. For each geographical area selected, randomly sample and then combine to give an overall sample.

Detailed Critical Sector Assessments by Specialists

This is necessary for evaluations of water supply and electric power and can be performed by staff from within or outside of these systems.²

Assessing the effect of a disaster on health entails addressing injuries, missing persons, illnesses, and death rates. Rapid assessment of primary injuries should estimate the number of persons injured and the severity, types, and sites of injuries. Primary injuries are those that are the result of the disaster itself, whereas secondary injuries occur during the postimpact phase of a disaster, such as injuries related to the clean-up. Analysis of where survivors seek care for such injuries provides one major data source.

The severity of a disaster is also closely related to the number of persons missing. Though difficult to obtain precise numbers, preliminary data can come from families as well as estimates from search teams, such as the fire department.

Even though communicable diseases are relatively rare in the immediate days after a disaster, surveyors should identify pathogens already present and pose a danger of spreading. Assessors should also design a preliminary plan for the best measures for disease control.

In emergencies, mortality is usually limited to reports of bodies recovered. Data should also include age- and sex-specific death rates, causes, and risk factors.⁸ For example, in complex humanitarian situations, crude mortality rates (CMR) can be measured by designating a burial site and using guards to count burials. Death rates should usually be reported as per 10,000 per day. Generally speaking, rates for emergencies such as humanitarian crises are approximately 0.4 to 0.6 deaths per 10,000 per day. A rate greater than 1.0 is considered elevated, and a rate of more than 2.0 is considered critical.⁹ Rapid-onset disasters will obviously have more front-end mortality rates.

Besides assessing the effect of a disaster on health, evaluating the potential effect on health services is also important. The top priority is determining the extent of damage to medical services and which medical facilities are still functioning. Surveyors should gather data regarding location and type of facilities, structural integrity postevent, capacity, injuries and deaths of staff, and any gaps in personnel or supplies. If time permits, data should also be collected concerning injuries treated at facilities, the need to evacuate patients for specialized care, and the types of medicines and other supplies most urgently needed.

Beyond health assessment, surveyors must also examine the integrity of the environmental situation postimpact. Analysis of water supply, sanitation, shelter, and transport is essential. Adequate supply of clean water is

of paramount importance, so particular attention should be made to estimate the size of communities without water, potentially contaminated sources of water, and the magnitude of damage to water supplies.

Challenges

Most assuredly, those performing rapid assessments face large obstacles. There may be blocked access to restricted areas, physical danger, nonstandardized reporting, and inaccurate baseline information.⁴ Data are usually collected rapidly under extremely adverse conditions, and sources of information must be integrated.⁷ Given the constraints of time, pressure, and limited initial research resources, it is likely that more accurate data will be collected during later phases, such as rehabilitation and recovery. Hence, needs assessment has to be an ongoing procedure.¹⁰ Consequently, those reviewing the information must understand the data-gathering methodologies, their inherent limitations, and sources of bias.²

Analyzing and Presenting Data

Data analysis should be performed with the use of standard techniques to ensure comparability with other situations. Analysis should be as specific as possible to facilitate the design of appropriate interventions. Presentation of data should be done in a standardized manner, with results that clearly indicate the greatest priorities for the response organization. All results should be widely distributed so that information can be verified and/or complemented. In general, the following format can be used as a standard for a presentation⁸:

- Reason for emergency
- Area affected
- Description of community affected, including injuries and deaths
- Impact of disaster (e.g., daily mortality, financial losses projected)
- Existing resources
- Additional requirements—immediate, medium, and long term

Despite the time constraints and difficulty in collecting data under chaotic environments, it is imperative that final analysis and presentation be as clear as possible, given that relief funding and response will directly result from how the data are reported.

PITFALLS

One major challenge of rapid needs assessment is finding a suitable body or organization with sufficient credibility or authority to disseminate the information and to ensure that the humanitarian response reflects the findings of the assessment. If assessments are not properly linked with decision makers, they are reduced to mere hospital records rather than critical information. Such surveys need credibility and coordination with other agencies to avoid duplicated efforts. A major pitfall is that they are often performed too late, and as a result,

their findings may be ignored. A second pitfall is that they are often performed by those without appropriate skills.⁵ Poor data collection and analysis are possibly worse than no data at all. A third pitfall is when assessment focuses on areas thought to be most affected instead of taking an overview of the entire area. This is problematic in two ways: first, the sites thought to be worst off may not actually be the most affected. Secondly, by focusing on the hardest-hit areas, there will be biased reporting and subsequent miscalculation of mortality. In general, bias can be a serious problem in rapid needs assessments during disasters. Sample sizes are often too small and not random. Furthermore, obtaining information based on hospitals or clinics can be misleading because those who seek care may not be the ones who actually need care the most because many in need cannot or do not visit health facilities.⁶

Standardized disaster surveillance algorithms have great potential to rapidly identify the acute needs of populations in the midst of disasters and to direct resources to areas most in need during the response and recovery phases.¹¹ Though such assessments are conducted amidst the upheaval of a disaster, it is imperative that experienced surveyors take a rational, systematic approach to their surveillance. It is such information that will ultimately guide intervention immediately and for future disasters, thereby directly contributing to the prevention of morbidity and mortality.

Disaster Communications

Khama D. Ennis-Holcombe

Facilitating efficient and effective communications is integral to the success of disaster management. Preparations for proper communications should begin long before the first “911” telephone call is made by anticipating and exploring potential communications needs. Communications infrastructure must then be established and tested before it is implemented.

The planning necessary for medical facilities to provide adequate communications in the event of a disaster or mass casualty incident is described in this chapter.

HISTORICAL PERSPECTIVE

At one time, the U.S. government’s response to disasters involved dozens of federal agencies handling various individual components. Communications planning was rarely addressed explicitly. Instead, often the assumption was that existing communications infrastructure would be sufficient.

In 1979, President Jimmy Carter created the Federal Emergency Management Agency (FEMA) to coordinate domestic disaster response. Although FEMA represented a consolidation of response efforts, communications planning initially was not directly addressed. Furthermore, disaster management remained largely focused on natural catastrophes, such as hurricanes and earthquakes, or unintentional manmade events, including oil spills and radiation leaks.¹

With the terrorist attacks of Sept. 11, 2001, the United States experienced unprecedented challenges in domestic disaster management, including a substantial strain on its communications systems. Within minutes of the first plane hitting the World Trade Center, the New York City Police Department established command central in a conference room at Bellevue Hospital’s emergency department and began coordinating with emergency medical services. As the media and public picked up on events, telephone lines became jammed and connections were unreliable. Additionally, the Emergency Operations Center that had been designed to handle large-scale disasters affecting New York City was evacuated and most of its structures were destroyed; it had been located at 7 World Trade Center.² Communications within the emergency department grew difficult as misinformation

regarding the attacks circulated. Police and administrators were able to correspond through direct conversation, radios, and pagers; however, cell phones and land lines remained unreliable.

In the wake of Sept. 11, many changes have taken place in U.S. disaster management. The Department of Homeland Security was established, bringing FEMA under its auspices. With this reorganization, the conception of disasters has been expanded to focus on intentional terrorist acts, and greater attention has been paid to establishing and protecting emergency communications infrastructure.³

CURRENT PRACTICE

There are numerous means of communicating during emergencies, including the standard systems at given facilities and backup resources.⁴

The National Incident Management System (NIMS) was approved in March 2004 as a means to coordinate first responder disaster management between federal, state, and local levels.^{5,6} One goal of NIMS is to ensure that the systems necessary for disaster management are in place so that time is not lost devising a plan during a time of need. One of the cornerstones of the communications guidelines is that local systems comply with national interoperable communications standards. A system that works perfectly in one area but cannot interact successfully with neighboring areas and additional agencies is likely to be of limited use. Local systems should be able to fit into a larger scheme of communications when needs exceed local capabilities to interface with expanded disaster response.

There are multiple formats for regional emergency response systems. In most situations, a 911 telephone call is routed through a public safety answering point (PSAP), sometimes at the police department, before being referred to the agency or agencies that will provide initial response, including fire, police, and emergency medical services.⁷ These systems use technologies for their operations, including a radio and telephone with originator site localization. The location from which a call is being made is immediately available, with the exception of many cellular phone calls. First responders can be

notified immediately, and hospitals also can be notified of potential patients.

Hospitals with emergency departments have means by which ambulances can call in entry notifications. Such calls can be placed while ambulances are en route and allow the facility time to prepare for the patient. In most areas, this communication is based on radio transmissions on ultra high frequency (UHF) and very high frequency (VHF) that are broadcast via radio towers located at specific sites throughout a service region. CMED (Coordinated Medical Emergency Direction) is one such system in operation in Massachusetts and Connecticut. UHF and VHF systems both vary widely. For example, a 24-watt transmitter can transmit signals up to a distance of 50 miles; however, this distance can be increased substantially by a relay tower, and most towers in use are much more powerful.

Medical facility plans are initiated from the moment of disaster notification, based on the patients that may present. A designated regional hierarchy for command and a location for command central will enhance communication efficiency for individual medical facilities. In some systems, the role of incident commander (IC) is fulfilled by the highest-ranked person within the first unit to respond. Within an emergency department, the person in charge may be the most senior attending physician present. Communication and coordination with other local medical facilities are priorities for the IC to ensure the best care for patients.

In addition to establishing a hierarchy, it is also essential to clarify the means by which information will be relayed. This includes communications within any given institution and between multiple institutions and agencies. Within a hospital, for example, there are means to alert the chiefs of each department of potential disasters. Overhead announcements are often possible, but text paging is a simpler and arguably better means of communicating this information. A list of key personnel is distributed to page operators, and in the event of a disaster, a single message can be sent to all parties via a group page. This is an approach that requires advance discussion and preparation but one that can save considerable time and minimize confusion. Text paging may also be an effective means of communication within individual departments.

The IC will assign roles to senior staff present. Areas to be addressed should include the following:

- Media communications
- Interfacility communications
- Intrafacility/interdepartmental communications
- Emergency department medical care
- Transfer of stabilized patients out of the emergency department
- Communications between the emergency department and the hospital command center

One person is often assigned to supervise and coordinate each of these tasks. In many cases, hospitals already have public relations staff members who handle media communications so that the main focus of practitioners can remain on patient care. Additionally, the local IC must be able to maintain two-way communication with

the disaster site. Information that should be prioritized in such communications includes emergency department capacity, hospital capacity, and potential hazards.

Interfacility communications may provide relief when a disaster overwhelms a medical facility. E-mail, telephone, and radio communications are excellent means by which hospitals can maintain contact and ensure that patient care is optimally coordinated. For example, if two hospitals are fairly close in location, specific patients may be directed to the site that is best equipped to manage their presenting concerns. In another scenario, if evidence of potential hazards to caretakers becomes apparent at one facility, it is essential that other facilities at risk be notified. This is especially important, given increasing concerns about biological, chemical, and radiological weapons.

A robust intrahospital communications system is beneficial to normal hospital operations in the absence of disaster. These systems may be used to facilitate movement of patients in the hospital and assist in coordinating tasks that could increase overall efficiency of operations.

Whether a disaster is natural or manmade, it may present enormous stress for all response workers involved. Accurate communications regarding the status of events can serve to minimize confusion. Even though effective communication should be a goal in any workplace, it is crucial in disaster management.

All pathways of communication should be designed to function both up and down the chain of command. Nurses, residents, and physicians should be able to discuss trends or concerns regarding patients with their supervisors, who can then relay these details to superiors to avoid loss of valuable information.

Also a link in the loop of communications and information-gathering is the patients themselves. Patient populations, including the methods of communication that they are most likely to use for health systems information, are elements that require consideration in communication plans.⁸ During the August 1999 earthquake in Turkey, which left more than 17,000 people dead, one needs assessment team found that 81% of the population relied on word of mouth for communications, and (only) 23% relied on public address systems, 20% on television, and 15% on radio.⁹

PITFALLS AND STRATEGIES

There are many resources available to reinforce health systems communications. The Centers for Disease Control and Prevention has established the Health Alert Networks, which aims to ensure high-speed Internet access for local health officials, increase capacity for secure communications, improve early warning broadcast alert systems, and optimize general organizational capacity of local systems.

To allow for the efficient transmission of airwaves, radio towers require a degree of unobstructed space; this lack of obstruction makes them difficult to protect. Even though this type of infrastructure presents a vulnerability, strategic duplication of radio towers may serve as a buffer in the event of distress.

If a local system is overwhelmed by the scope of a disaster, federal backup is available. FEMA has established Mobile Emergency Response Support (MERS) systems to provide support throughout the United States. In this system, the country is divided into 10 regions. Mobile units are located in each region and can provide assistance in the form of telecommunications with satellite, line of sight microwave, and radio (high frequency [HF], UHF, and VHF) communications as well as generators in the event of power failure. HF radio is used to communicate with federal, state, and local emergency centers via the FEMA National Radio Network and FEMA Regional Radio Network. VHF and UHF can be used for local radio communications.¹⁰

In addition to these established systems, in California, there is also a reserve radio system, called the Hospital Disaster Support Communications System and RACES (radio amateur civil emergency services), that uses certified volunteer personnel to perform many tasks related to communications.¹¹ This public service is intended to assist communications among government agencies and healthcare facilities in times of extraordinary need and could potentially be expanded and developed across the country.

Power outages can occur at any time, in any location. They can be due to system overload during times of excessive use, such as the 2003 blackouts in the Northeastern United States, or to interruptions in service caused by intentional destruction. Regardless of the cause, the possibility of power loss must be anticipated by establishing backup generators that will activate immediately on power interruption. Such generators should be maintained and tested on a regular basis. One aspect of disaster management for which electricity is essential is the operation of most communications technologies and medical equipment.

Finally, testing the plan at regular intervals ensures competency among users. It is even desirable to incorporate as much of disaster communications systems as possible into routine daily operations. In Rhode Island, a disaster communications system that links all of the acute-care hospitals in the state is used three times a day, every day, to provide ambulance diversion status.

SUMMARY

The most important principles of communications related to disaster management are preparation, efficiency, and backup plans. Preparation will ensure that disaster management workers know their responsibilities and how to complete them. Efficient communications systems at each facility will optimize the use of technology and help to maintain an effective chain of command. Finally, establishing backup plans will ensure that response workers can carry out their tasks, even in the midst of unpredictable concerns that are so often part of both natural and man-made disasters. In essence, the more focus that is given to communications before a disaster, the better workers will be able to carry out their roles in the event that a disaster occurs.

Media Relations*

Daniel F. Noltkamper

Emergency management organizations and media representatives have different and, not infrequently, competing roles in a disaster.¹ Emergency management organizations are focused on response, containment, search and rescue, recovery, and rehabilitation, whereas the media concentrates on gathering information and disseminating it to the public. Both have their own objectives, and even though not the same, they can be complementary if coordinated properly.

As recent events have unfortunately demonstrated, a disaster provides all the ingredients of a hit reality television show or movie. It includes drama, challenges, action, heroism, and suffering.² These qualities make it of interest to a national and sometimes international audience and may provide the opportunity for certain organizations or individuals to gain status or popularity. Although often an unintended consequence, this can pose a problem when it becomes a primary motivator. At the World Conference on Natural Disaster Reduction and the Roundtable on the Media, Scientific Information, and Disasters, Dr. Olavi Elo, director of the International Decade for Natural Disaster Reduction (IDNDR), stated: "We are not helped by how the priorities are perceived in the eyes of the media: human misery is far more newsworthy than a population made safe and sound."¹ One study estimated that 25% of all news stories involve natural disasters, technological hazards, and civil disturbances.²

New technology has allowed easier, and often instantaneous, broadcasting to a larger population, and the proliferation of television channels and Internet reporting has increased the competition for newsworthy items.³ Journalists and media organizations have a job to perform, employers and advertisers to satisfy, and a public to inform.

Disaster response organizations work to mitigate hazards, protect the public, restore infrastructures, and assist in recovery. Many times this is completed with small, local agencies in the first few days. Although they need to get information to the people at risk, they may be overtaxed with their other duties. In past times, journal-

ists were seen as a drain on resources and obstruction of emergency response. Attitudes about the media have changed, and a role for the media in disaster management has been identified.

The media need to be included in disaster planning. Their participation will improve their understanding of the response plan, how they can assist, and establish points of contact. An early, good relationship will lead to better cooperation when emergencies present. Even though panic is rare in disasters,⁴ properly communicated media information will lessen the disruption produced by horrific events and will reduce individual anxiety.

HISTORICAL PERSPECTIVE

Print and Broadcast

The first American newspaper, known as *Publick Occurrences*, was established in 1690 and was quickly suppressed; the first successful newspaper was the *Boston News-Letter*, which started in 1704. One of the greatest natural disasters of the 20th century was the Galveston, Texas, hurricane of 1900. The *Daily News*, a local Galveston paper, ran a one-paragraph article on page 3 the day the hurricane struck, yet the category 4 hurricane left 6000 people dead and destroyed 3600 homes. In 1906 an earthquake struck San Francisco, and secondary fires disabled all three newspapers in the city. The three competitors teamed up to publish the *Call-Chronicle-Examiner* in Oakland and distributed the paper containing the account the next day in San Francisco.⁵

One of radio broadcasting's greatest moments was May 6, 1937, when reporter Herb Morrison recorded a live account of the Hindenburg disaster in Lakehurst, N.J. It was later aired by WLS of Chicago.⁶

Television's first broadcast of a disaster was also a delayed broadcast. On March 10, 1933, an earthquake struck Los Angeles. Pictures of the damage were aired the next day by station W6XAO. The first telecast of an unscheduled event occurred in New York in 1938 when a mobile unit for RCA was in a park in Queens when a fire broke out on Ward's Island.

*The views expressed in this article are those of the author and do not necessarily reflect the official policy or position of the Department of the Navy, Department of Defense, or the U.S. government.

Emergency Advisory System

President Harry S. Truman approved the CONELRAD (Control of Electromagnetic Radiation) program in 1951 to deliver emergency broadcasts over television and AM and FM radio stations. It allowed the president to deliver a message via the mass media to the public.⁷ In 1963, President Kennedy converted CONELRAD to the Emergency Broadcast System. It became an interagency effort of the Federal Communications Commission (FCC), Federal Emergency Management Agency (FEMA), and National Weather Service (NWS). He permitted it to be used for state and local emergencies.

Although never used for war announcements or a nuclear attack, as originally intended, the Emergency Broadcast System was used just over 20,000 times between 1976 and 1996 to broadcast civil emergencies. Most (85%) of these announcements were weather-related. In 1997, it was renamed the Emergency Alert System (EAS), and in 1998, it included cable television systems with more than 10,000 subscribers. The EAS also includes the U.S. Weather Bureau tone-alert radio system. FEMA provides information for system use by state and local emergency planners.^{2,8-10}

CURRENT PRACTICE

Media: Benefit or Hindrance

The media have the potential to be both a hindrance and a benefit in disaster response. Every disaster response or emergency management system must have plans to deal with the media. Although they may often get in the way, the media may also afford a remarkable opportunity for communication. The media is a cost-effective means of transmitting information to the public to save lives, reduce damage to property, and increase public awareness of hazards.¹ Sirens may provide an initial alert, but most individuals then turn to the broadcast media to determine if the threat is real and obtain more information. In disasters in which warnings are possible, if used properly with careful planning, the media can be a factor in preventing injury or death by serving as an initial warning source for the public. During a disaster, agencies involved directly in the response may use media information as a resource. This may be due to overloaded radio communications or because views from a media helicopter are being shown. Many hospitals first learn about disasters from media sources and initiate preparations for receiving casualties based on the broadcasted accounts of the event.¹¹

The media can serve many positive functions in disaster response. They can convey instructions to the target population for protection and evacuation, which can reduce the need for further emergency response personnel. Although often counter to their mission, reporters and news anchors may provide reassurance to the masses when specifically requested to do so. Another important consequence of media coverage is that it may stimulate donations from areas not directly affected by the disaster and initiate government financial

support.² Political and public support may increase due to the coverage and draw attention to future hazards.³ If the media report on areas unaffected by the disaster, this may result in a reduction of inquiries from concerned persons outside of the immediate area of the disaster. Finally, follow-up stories may facilitate future emergency services funding and assist in the re-election efforts of politicians in the disaster area.²

The news media can stimulate public interest in donations and many times initiate their own “drives.” Many times, local leaders suggest donations while being interviewed. Even though the intentions are good, there are many instances in which media involvement regarding donations has turned into a problem. Donations require manpower and storage. Many items may rot if adequate storage is unavailable. Manpower is then needed to dispose of goods that can become a public health issue. Trucks delivering the goods increase traffic into the area. Often, undesired items are received and require storage or disposal. On the other hand, as items arrive, the media may report on the large amount of outside support. False perceptions by the public may lead to a halt in donations of still-needed supplies.¹²

Not all consider the media an easy partner in disaster situations. A major concern is increased resource allocation that diverts attention away from command and control, casualty care, search and rescue, and evacuation. Resources affected can include response personnel and public officials (who are requested for interviews and tours), transportation, communication facilities, electrical power and lighting, work spaces, housing, food, and water. The media may pressure officials for numbers pertaining to casualties and damage. If conflicting numbers are presented, it could be portrayed as incompetence on the part of the command and control organization. Officials may also feel pressured by the media to make decisions prematurely.²

Exaggeration may be perceived if the media reports on interesting news items only. Examples include showing a damaged section repeatedly but not showing the unaffected area or reporting looting to be widespread, even if it is not. This is especially true if multiple sources report on the same few instances. Panic is often reported by the media even when it has not occurred. These exaggerations lead to increased inquiries by loved ones outside the area, taxing resources already engaged in other aspects of the emergency. Evacuations may be hampered as people watch pictures of long lines at gas stations and crowded highways and decide not to evacuate.³

Media helicopters have been known to assist with search and rescue missions, help analyze disasters, and provide current information on the situation for officials. As of October 2001 there were 200 reported helicopters used for media reporting; 125 of these were in major cities.¹³ However, with helicopter use to report stories, there have been concerns raised about the crowding of airspaces and possible further damage to degraded structures. The Federal Aviation Administration (FAA) has the ability to create temporary flight restrictions over scenes of accidents, disasters, and special events under Federal Aviation Regulation 14 CFR Section 91.137 allows for safe operating of disaster relief aircraft. To protect fragile structures

and people inside who are at risk of injury in the event of collapse, the suggested restricted airspace is 2000 feet above and a radius of 1 nautical mile from the area. In addition to rotorwash and vibration possibly harming buildings, the noise of aircraft could interfere with sensors being used to locate trapped individuals.¹⁴

Media Formats

Media types can be separated into broadcast and print. Broadcast media includes television and radio. Print involves newspapers and magazines. Internet reporting is a hybrid of both types. There are differences in their needs and roles in disaster reporting. They will all show up at a disaster to fill the public's need for news. It is also their livelihood, and they are professionals at seeking out newsworthy stories.

The 24-hour satellite and cable television news stations have a need to fill their airtime with items that capture and inform viewers. Local news programs compete to fulfill their obligation to nearby residents, and many people stay tuned to the network news afterward. No area is outside of the reach of television reporting when helicopters and satellite-dish trucks are used. Technology has created smaller and cheaper cameras and transmitting equipment. Fewer crew members are required, making the teams more mobile. When local stations are incapacitated, information can be transmitted to stations in unaffected areas. Those stations can, in turn, send reports back into the affected zones.^{2,15,16}

Television is visual, and stations desire graphic images to capture viewers. Most disasters provide many images useful for this purpose. Action is constantly occurring and provides a good background for reporters. Television media have a need for short, succinct reports from officials—approximately a 20- to 30-second report that covers the most important facts. They also will need updates approximately 2 hours before their scheduled news programs air. In some instances they may interrupt regular programming to bring breaking news stories to attention. Since television is visual, officials should remain calm in their appearance and manner while giving interviews.

Radio provides the ability to get the word out quickly. Radio media also can interrupt regular programming to bring unfolding stories to the public. Their desire also is usually brief and concise reports from officials.³ Since audio is their form of media, they may wish for some degree of background noise, but it may interfere with the message being relayed.¹⁶

Print media does not have the hour-to-hour deadlines seen with broadcast media so they may be interested in more details and background information.² Names of officials and technical words should be spelled out to print media. They may run the disaster stories for a longer period and in more detail, which may assist in future funding. They also have less equipment requirements and rely less on power sources at the site. When Guam was struck by super typhoon Pongsona in December 2002, it knocked out power and telephone lines, disabling television and radio media. Using a computer and generator, the *Pacific Daily News* was able to

publish the effects of the storm in print and on its Web site, using a server in Virginia. The newspaper was delivered to residents in shelters since most roads were impassable. Loved ones outside of Guam, the U.S. Weather Service, and the FAA were able to obtain information from the Web site.¹⁷ In this instance, the form of media with the least technology requirements was able to get information to the public.

Internet reporting has features of both broadcast and print media. Internet reports can be presented 24 hours a day and combine visual, audio, and printed forms of communication. Internet accessibility affords disaster response officials the opportunity to provide information and updates to the public and media using fewer resources. Preprinted public safety announcements about multiple hazards that could exist in a disaster situation can be placed on an organization's Web site. Electronic mail groups to media contacts can speed information updates.

In all types of media, special consideration should be given to special groups in the affected areas. Language and cultural barriers should be addressed as well as hurdles involving sight- and hearing-impaired individuals.²

Whether dealing with broadcast or print media personnel, disaster officials should get contact names, phone numbers, and e-mail addresses to provide updates as they arise. Also, any background materials about the region affected would be helpful. They may also provide reports with unique aspects and human-interest stories that stimulate attention from areas beyond the local region.

National and Local Media Differences

National media organizations are interested in the overall picture. They also may provide stories with unique aspects and human-interest stories. Questions may be asked about prominent figures, historical and important structures, and significant national treasures. Their resources outweigh those of local media agencies, and they may quickly overwhelm and capture official attention initially given to the local groups. Their resources include star correspondents; subject-matter experts; and logistical coordinators for lodging, power, and telephone lines. Many national networks will also cooperate together because they interact frequently.

Reporters from local media organizations are usually the first on the scene. Many live in or near the disaster area and understand the local impact. They may be present during all phases of the disaster (e.g., mitigation, planning, response, and recovery). During the mitigation phase, they may report on local hazards and minimize the risk of disaster. Reporting of hazards and risks may lead to political and financial support for emergency response organizations. They should be involved in the disaster planning phase, where they can come to a better understanding of the emergency response plan and establish points of contact. In the response phase, they can offer initial warnings of impending emergencies, public safety announcements, evacuation instructions, utility limitations, and information on the progress of the response. Their long-range reporting after the disaster can assist in the recovery phase.^{2,18,19} In general, the local

media are more interested in their community's welfare than are the national media.¹¹

Many times, local news agencies are displaced by the attention given to the national media organizations. It should be remembered that the local reporters are a valuable resource. As relationships and friendships are formed, they may demonstrate more favorable reporting of the emergency response. They can assist in coordinating media pools and press releases as well as tours. If involved in the planning phase, they can become an extension of the usually overtasked public information officer (PIO).

Public Information Officer

The PIO reports to the incident commander in the Incident Command System. The PIO is responsible for developing and maintaining a media contact list, scheduling interviews, selecting and preparing appropriate team members for the interviews, escorting media and VIPs through the site, preparing and issuing press releases, and gathering and verifying information. To complete these tasks, the PIO must have a knowledge of local plans, disaster management concepts, capabilities of the response team, and the state and federal response plan.³

Specialized training as a PIO can make the incident commander's representative a valuable asset. The PIO must be equipped with resources such as computers and Internet and telephone access. In some instances, a media relations team may be required. The PIOs from all agencies involved in the disaster response may form the team and may appoint a single spokesperson to disseminate coordinated information.¹¹ An experienced and well-equipped PIO may be able to defuse many difficult situations involving the press. The PIO should remain accessible to the media at all times and should establish contact with counterparts at other response organizations, such as hospitals and government organizations.¹⁹ In many situations, the PIO can suggest interesting stories to the media. This may include stories that educate the public on the role of emergency management planners and disaster responders.

Web sites can assist the PIO in disseminating information. Preprinted public safety advisories and press releases can be posted on the Web site. These may ensure more accurate information is supplied to the press. News agencies can remain updated through the Web site or by e-mail. A 24-hour hot line with pre-recorded messages can also be useful. The PIO should also maintain a communications log that documents all interactions with the press. It should include who said what and when it was said to ensure accurate information is provided during the course of the disaster. This may be used in the recovery phase to update contact lists and produce lessons learned. To improve future plans, consider a survey of local and national media organizations who reported on the disaster.¹⁸

Press Conferences

Information should be provided as quickly as possible so it may be passed to the public. A media center can meet

this need. The center should be established in a safe location to protect the media from hazards, including infectious casualties. Access to food, drinks, and restrooms should be provided. In certain locations, such as hospitals, an area where cellular phones may be used without interfering with patient monitoring should be identified. Most media organizations share information in a major disaster and will appreciate a single location to gather the information. This allows quick access to a lot of information and assists reporters in meeting deadlines.^{20,21}

Centralize information as much as possible to send out one consistent message. One identified person, who comes across as trustworthy, will build credibility. That person should be knowledgeable about the disaster response process but may invite other experts to assist as needed. The speaker should be from the command post if possible so the news can report the information as originating from an official source. Names and titles of those speaking, as well as background information, can be disseminated in advance. Question cards can be distributed to the press before the conference, and repetitive questions can be answered by the lead spokesperson. During the initial conference, the schedule for future ones may be announced.²¹

If the center becomes too crowded, media pools may be established. One reporter or a small group of reporters attends the conference and shares the information gathered with media members who were not at the conferences. This also works for tours of the damaged areas once safe access is established. This process is well accepted and should involve one representative each from television, radio, and print. A local reporter involved in the planning stages may be ideal in coordinating the pool and tour representatives.

Interview Basics

Questions from the media are fairly predictable and can be prepared for in advance. Appear calm and professional. Avoid anger and frustration. Think about your answers and avoid rushing; the media can edit out pauses. Speak about the response teams involved, the disaster and its effect, and any casualties that are known. Avoid speculation; specific numbers; technical jargon; and phrases such as "off the record," "I think," and "no comment." Inform the press when you don't know the answer to their question and offer to provide it later. Take the offensive, and offer all available information initially. A leading statement, such as "The most important information is..." will satisfy many reporters' needs, especially those in broadcast media.^{3,22} The interview is also a chance to verify information and expose myths. The media will often withhold information that the speaker identifies as being dangerous for public consumption, but care should be taken to emphasize that the information should not be released. Critical messages to convey include the following²³:

- Personnel in senior leadership know what they are dealing with
- Emergency management knows how to respond to the disaster

- The response plan is
- The public needs to know to protect itself
- (If terrorism is involved), steps are being taken to find the guilty parties

Other expected questions will involve who is in charge of the disaster response, whether the situation is under control, how the injured are being cared for, why did this happen and was it preventable, and what else can be expected. Identify locations where other information can be obtained, such as Web sites or hot lines.

Other details may be requested during the interview. Casualty questions may include how many were killed or injured, how many escaped injury, and were any prominent figures involved. Property damage details may focus on important buildings, arts and treasures, prominent owners, measures to protect other properties, and insurance issues. Response questions focus on who discovered the disaster first, who responded and how quickly, whether there were any heroic acts, and where the homeless and displaced are being taken. Questions about cause may involve any previous indications of problems or threats and whether any criminal investigations or lawsuits have been initiated. Other possible questions include whether blasts or explosions were detected, were crimes or violence observed, were there any acts of self-rescue, and the expected extent and duration of the response.²

PITFALLS

1. *Not including the media in disaster planning:* Local resources can assist in obtaining public support and funding, educating and informing the public, and assisting with media pools. Also do not ignore the local media organizations when national reporters arrive.
2. *Assuming the media will not appear at the disaster:* They will come, and large disasters may include international representatives.
3. *Sequestering and ignoring the media:* Without information, the media will create stories based on what little facts they have.
4. *Using an untrained, inexperienced PIO:* Emergency management organizations are best represented when a trained, experienced PIO can organize and guide the media.
5. *Hiding the truth:* Using the phrase “no comment” makes the media and public suspicious that there are hidden issues.
6. *Going “off the record”:* Odds are that “off-the-record” comments will appear in print or broadcast.
7. *Speculating:* Any assumptions may be incorrect, and when the true information is discovered, it may reflect incompetence.
8. *Failing to check with the potential recipient organizations before issuing appeals for donations or volunteers on their behalf:* Be proactive in announcing when donations or volunteers are not needed.

9. *Failing to provide details on the disaster that will allow the public to determine whether their friends and family are safe:* These details can include maps of the affected area with specific comments on areas not involved. This will reduce the number of inquiries to officials involved in the disaster response.

Managing Volunteers and Donations

Andrew M. Milsten

Offering help to people in need is a basic human instinct. During the war in Yugoslavia (1999), thousands of people were able to survive because of donations from foreign governments and private individuals and organizations.¹ Donations and volunteerism can be a help or hindrance, though, depending on whether the right amount of goods, people, and materials are sent to the disaster region. There is a common misperception that when a disaster occurs, people should send everything they have as rapidly as possible. Misperceptions such as this can result in large amounts of wasted human and nonhuman resources.

There are two types of donations: in-cash and in-kind. Cash donations are often ideal because of flexibility and ease of coordination and because cash allows materials to be purchased through normal channels while supporting the local economy. The Internet has recently become an efficient method for obtaining cash donations. After the southeast Asia tsunami in 2004, large amounts of money were donated rapidly through the Internet, with sites such as Amazon.com collecting upwards of \$3 million within days of the event.² The downside to cash donations is that they are susceptible to misuse.¹ Donations in-kind are less standardized and, although immensely helpful, can cause problems unknown to the donor.¹ This chapter specifically examines disaster volunteerism and in-kind drug and blood donations.

INTRODUCTION TO DONATIONS

Drug Donations

During times of crisis many different entities provide drug donations, including private individuals and companies, nongovernment organizations (NGOs), international agencies such as the United Nations (UN), and foreign governments.³ The literature on this subject, which focuses on disasters as well as complex humanitarian emergencies such as refugee situations, indicates that many disaster-stricken regions become dependent on foreign medical aid (for both acute emergencies and long-term aid).^{3,4} Drug donations are a complex issue, however, and although such donations can help disaster-stricken countries retain their treatment quality and

meet healthcare needs, numerous negative outcomes also can occur. For example, the common misperception that it is better to send any drug rather than none at all results in often-inappropriate medical materials arriving in the recipient country.⁵ Despite the donors' good intentions, donated drugs are often inappropriate to treat local diseases and are nutritionally inadequate (e.g., commercial soft drinks sent to treat cholera in Zaire in 1994).⁶⁻⁸ In addition, a practice known as "drug dumping" often results in large quantities of useless drugs arriving in the disaster-struck region.^{9,10} *Drug dumping*, a term meaning the donation of defective products, has been studied both in terms of quantity and quality (e.g., amount, appropriateness, usability).^{3,11}

HISTORICAL PERSPECTIVE

Drug Donations

Standardization and management of medical donations have been issues for years and were under the domain of the Red Cross Movement until 1957. After World War II, national and international organizations focused on these issues. It was not until after the Persian Gulf War, however, that emergency relief deficiency came under the scrutiny of the UN.¹²

Starting in 1976, reports began appearing about the deleterious effects that large amounts of inappropriate donated drugs can have on a recipient country. In 1996, the UN designated the World Health Organization (WHO) as coordinator of health-related international agency work.¹² WHO took several actions in Bosnia to facilitate this mission, including establishing interagency coordination committees, assessing needs, coordinating drug supplies, disseminating drug lists and guidelines, and promoting the use of essential drug kits.¹³ Despite WHO's efforts, drug donations to Bosnia and Herzegovina were criticized for the following^{1,3,14-16}:

- Being of low quality and frequently expired
- Adding to postwar chaos
- Being unequally distributed
- Allowing an NGO to deliver materials to an area that had recently received similar materials from a different NGO

- Often being inappropriate
- Allowing the media too big a role in swaying what donors gave and how much

Some authors believed that these criticisms were “elitist” and noted that, for example, drug expiration dates are extremely conservative and that a possible solution to the problem of expired drugs could be to “perhaps double the usual dose.”¹⁷ These authors also noted that human suffering would be worsened by not using donated drugs.¹⁷ The use of expired drugs generally has not been acceptable for reasons including problems related to toxic metabolites; unknown efficacy; opening the door to bad donation practices; loss of credibility for the donor; and violating the Basal Convention, which regulates the transnational movement of hazardous waste, including unused drugs, and its disposal and requires the owner, the receiver, and the transporter of any chemical that could be toxic, poisonous, or ecotoxic to get clearance from the relevant authority in charge of the Basal Convention.^{1,3,6,18}

Examples of inappropriate donation practices are shown in Table 35-1. During the Sudan war (1985) inappropriate pharmaceutical donations included contact lens solution, appetite stimulants, cholesterol-lowering drugs, and expired antibiotics.⁵ In Lithuania (1993), 11 women were temporarily blinded after taking a drug donated by Caritas (closantel—a veterinary anthelmintic) that was mistakenly given to treat endometriosis because of poor labeling.^{5,19} In Georgia (former USSR) (1995) 20 tons of expired silver sulfadiazine were received, and Eritrea, Africa, (1994) received seven truckloads of expired aspirin, a shipping container of unsolicited cardiovascular drugs with 2 months to expire, and 30,000 bottles of expired amino acid infusion (that could not be disposed of due to the smell).^{5,20} Other examples of completely

nonsensical donations—although not drug donations per se—include bikinis sent to Gujarat, India (earthquake), crates of double-D bras sent to Kobi, Japan (earthquake), breast implants sent to a hospital in Malawi, Africa, and ski jackets sent to Sri Lanka.^{19,21}

U.S. pharmaceutical companies often are saddled with a negative image for their poor donation practices, which is not entirely unjustified. For example, Eli Lilly donated 6 million poorly labeled cefaclor (Ceclor CD) tablets, even though the tablets were nearing expiration and had not received approval from the Food and Drug Administration for sale in the United States.¹⁹ There are worthwhile long-term sustainable U.S. pharmaceutical programs, however, including Merck’s Mectizan Donation Program (providing free drugs [ivermectin] to treat river blindness since 1988); Sanofi Aventis’ partnership with WHO and the medical NGO Médecins Sans Frontières to distribute medicines for African sleeping sickness; and Roche’s policy to make HIV protease inhibitors (nelfinavir and saquinavir) available to developing countries at much reduced costs.^{19,22}

In 1999, WHO identified six specific problems associated with drug donations, which led to the development of “good practice” guidelines.^{15,23,24} WHO identified the following problems^{5,23,25}:

1. Donation of drugs irrelevant to the recipient country’s situation
2. Unsorted and poorly labeled drugs
3. Low-quality drugs (e.g., expired, returns)
4. Ignorance of local administrative procedures
5. High custom charges to the recipient (due to high declared drug value)
6. Donation of incorrect quantities (too much of some drugs and too little of others).

TABLE 35-1 EXAMPLES OF DRUG DUMPING

YEAR	LOCATION	AMOUNT DONATED (METRIC TONS*)	INAPPROPRIATE AMOUNT	NOTES
1976 ⁹	Guatemala earthquake	100 (7000 cartons)	90% unsorted	1120 hours of sorting time
1984-1985 ³⁶	Ethiopia famine	Not listed	Not listed	US \$500,000 worth of inappropriate drugs were destroyed
1985 ⁴²	Mexico earthquake	1088 Drugs: 31% Food: 14% Supplies, clothes, and blankets: 24%		Heavy machinery 6%-14% (most needed)
1985-1987 ¹¹	Sudan famine	Not listed	8 million chloroquine and 500,000 piperazine were expired	380,000 Citramon tablets were banned Vitamins and baby food were not registered.
1989 ^{5,27}	Armenia earthquake	5000 Drugs: 65% IV: 20% Consumables: 15%	70% Expired: 8% Frozen: 4% Unsorted: 18% Useless: 11% Unidentifiable: 12%	Poorly labeled antibiotics (238 names in 21 languages) Sorting time was 6 months with 50 people
1992-1996 ³	Bosnia and Herzegovina	27,800-34,800	50%-60%	
1994-1997 ²³	Armenia, Haiti, and United Republic of Tanzania	16,500 shipments (no weight listed)	10%-42%	6% expired
2000 ¹⁹	Venezuela floods	Not listed	70%	\$16,000 spent to sort drugs

*1 metric ton = 2204.6 pounds; 1 ton is approximately 40 cubic feet.

Many authors agree with WHO's assessment and add other factors to consider.¹⁵ For instance, Berckmans³ noted three categories of donations that were sent to Bosnia and Herzegovina: those that conformed to WHO's interagency guidelines for drug donations, miscellaneous medicines (e.g., unsorted, free samples), and large quantities of donated drugs that were useless or unusable (e.g., 1961 plaster tape, WWII supplies). During the 1985 war in Sudan, the country received drugs that were in small packets and partly used (open blister packets).⁴ Another problem with donations to Sudan was that local doctors often were unfamiliar with newly introduced drugs. Further, once the stock of new drugs ran out, patients wished to continue the often more expensive drug, which led to treatment interruptions.⁴ In Croatia (1990-1994), it was found that drug donations led to "changes in therapeutic principles" as well as changes in prescribing patterns and organized drug acquisition at University Hospital Center of Rijeka (e.g., decreased use of cotimoxazole, ampicillin, and cephalexin and increased use of amoxicillin plus clavulanic acid, gentamycin, and cefuroxime).¹⁰ Médecins Sans Frontières also notes that the practice and culture of corporate drug donations do not encourage local production of generic drugs and may hinder the recipient countries' attempts at a sustainable cost-recovery program.¹⁹ Finally, Hogerzeil points out that donation of excessive quantities leads to stockpiling, pilfering, and black market sales.^{5,26}

There are many reasons to donate medical materials to a disaster-stricken region, and most donations are sent with good intentions.^{6,13} However, there are several non-altruistic reasons for donating drugs, such as avoiding drug destruction costs, publicity, disposing of surplus or wasted medicines, political pressure to take action (drug donations "film well"), tax benefits for donor companies and private voluntary organizations, and stimulating the market for certain products (brand recognition in a potential new market).^{3,6,15,9,25} Whether these motivations are viewed as morally corrupt and self-serving or well intentioned but gone awry depends on perspective and constitutes a debate beyond the scope of this chapter.

Whatever the reasons behind a donation, there are definite consequences to drug dumping, and the resource-strapped recipient country usually suffers them. It is difficult to store, sort, organize, and handle large quantities of donated medical supplies. Researchers studying the situation in Bosnia and Herzegovina had difficulty in locating unused medical supplies because the warehouses were subject to restricted access and their whereabouts were often unknown.³ There can also be high destruction costs associated with donating unusable drugs: 1 ton of drugs in Bosnia and Herzegovina cost US \$2000 to destroy, costing the recipient country \$34 million and requiring the construction of incinerator plants—a situation that occurred in Macedonia and Armenia as well.^{3,6,24,27} In cases in which the drugs are inappropriate to the situation but not unusable, the drugs could be shipped to another country rather than be destroyed; however, shipment can cost \$2 to \$4 million per 1000 metric ton.²⁴ Other less-tangible destruction costs include health and environmental hazards,

storage, handling, and transportation, which are often greater than the donated drugs.^{3,5} In the wake of the southeast Asia tsunami disaster of 2004, there were concerns about empty water bottles littering the environment as well as no-longer-needed medicines (morphine) being loose and uncontrolled in Sri Lanka.²¹ WHO has developed guidelines for the safe disposal of drugs, including the use of sanitary landfills, encapsulation, incineration, discharge to a sewer, high-temperature (1200°C) incinerators, and chemical waste treatment centers.^{6,13,24,27}

The Armenian earthquake situation vividly demonstrates the local costs associated with poor donation practices. In December 1988, Armenia, Turkey, was rocked by an earthquake (6.9 on the Richter scale) in an area populated by 700,000 people. Deaths were estimated between 24,000 and 60,000 people. Three days after the earthquake, international relief from 74 countries arrived, including 5000 tons of medical materials (valued at US \$55 million), money, and human resources.²⁷ Local resources in the ill-prepared region were depleted, and disorganization reigned. The Armenian airport handled 150 landings a day, where unaccompanied shipments were dropped onto the airstrip and left behind. Armenian personnel were quickly overwhelmed attempting to locate specific supplies amidst the sea of donations and to deliver medical materials to the field. It took 1 month to set up an efficient donation management strategy.²⁷ Pharmacists spent two-thirds of their time searching for appropriate drugs, and it took 50 people 6 months to sort the donations (mostly nonmedical personnel using pharmaceutical textbooks and cross-indexes to decipher the donated drugs).^{5,27} There were also problems handling large heavy packages, finding adequate storage space (32 new storage buildings were constructed that held 70% of donations while the rest were shipped to Moscow), and disposing of drugs destroyed by cold temperatures (4%).²⁷

CURRENT PRACTICE

Drug Donations

Suggested solutions to problems associated with drug donations are based primarily on basic disaster planning techniques, such as preparing for anticipated needs, recognizing that each disaster is different and that priorities change, and performing realistic needs analyses.^{28,29} Many have advocated for better communication of needs and the exchange of more reliable information between recipient countries and donors.^{5,6,13} Mitigation planning should be done by recipient countries to help strengthen legislative policies toward donors, centralize drug donations and emergency aid (using principles of good pharmacy practice), put registration and quality assurance procedures into place, and develop a national essential drugs list.^{3,5,23}

Pan American Health Organization (PAHO)/WHO's Supply Management System (SUMA, 1992) is a good example of an information management tool that could help disaster-stricken countries deal with donations

BOX 35-1 WHO GUIDELINES: CORE PRINCIPLES FOR DRUG DONATION

Maximum benefit to the recipient
 Respect for the wishes and authority of the recipient
 No double standards in drug quality
 Effective communication between donor and recipient

more effectively. To help disaster managers sort through large amounts of donations, SUMA uses simple tracking software. SUMA works by prioritizing and collecting data at donation entry points (airport, seaport, or border) and categorizing these items. Other SUMA team members gather data at warehouses and distribution centers and then electronically send this information to the central area. From this area, customized reports detailing donation activity and status can be generated.³⁰

WHO has taken the lead on setting standards for good donation practices with guidelines promulgated in 1999.²⁴ WHO started work on these guidelines in 1990 and finished them through an international consultative process involving more than 100 agencies.⁵ WHO's guidelines provide core donation principles and contain four categories (Box 35-1 and Table 35-2).^{5,14,23,31-33} WHO also maintains a list of essential drugs (the Model List, revised in 2003) and encourages each country to produce its own national drug list (focusing on safety, appropriateness, efficacy, and cost-effectiveness).^{6,34}

Although WHO's guidelines have not been followed on a consistent basis, such as in Albania, Rwanda, and Somalia, their acceptance appears to be growing and has led to a large change in donation practices.^{20,24,31} As Autier¹⁸ points out, however, the development of guidelines only will not be sufficient for effective coordination. For example, guidelines alone cannot resolve the problems associated with massive quantities of unsolicited donations, weak monitoring systems, high costs of dealing with useless drugs, training gaps, poor coordination, unclear responsibilities, local and traditional values not being respected, dependency on donated goods, and involvement of military personnel unfamiliar with humanitarian work (during the Kosovo crisis in 1999, NATO military staff were unaware of standard humanitarian distribution procedures).³⁵ Ideally, donation management and coordination would be carried out by small teams of experts who are familiar with disasters and able to continually adjust donation demands for community health needs. Organizations with minimal bureaucracy are best suited for this task, especially if they are willing to apply some donated monies earmarked for material purchases (such as drugs) to setting up a coordination system.¹⁸

WHO also developed the emergency health kit, a standardized kit containing sufficient drugs and medical supplies for 10,000 people and designed for immediate release to a refugee situation.^{5,36,37} UNICEF and the International Dispensaries Association stock emergency health kits as well.⁴ The emergency health kits were put together as a short-term use (3 months) commodity that could be used while more specific needs

TABLE 35-2 WHO DRUG DONATION GUIDELINES (1999)

Selection of drugs	<ul style="list-style-type: none"> All drug donations should be based on an expressed need and be relevant to the disease pattern in the recipient country. Drugs should not be sent without prior consent by the recipient. All donated drugs or their generic equivalents should be approved for use in the recipient country and appear on the national list of essential drugs, or, if a national list is not available, on the WHO Model List of Essential Drugs, unless specifically requested otherwise by the recipient. The presentation, strength, and formulation of donated drugs should, as much as possible, be similar to those of drugs commonly used in the recipient country.
Quality assurance and shelf life	<ul style="list-style-type: none"> All donated drugs should be obtained from a reliable source and comply with quality standards in both donor and recipient country. The WHO Certification Scheme on the Quality of Pharmaceutical Products Moving in International Commerce 7 should be used. No drugs should be donated that have been issued to patients and then returned to a pharmacy or elsewhere, or were given to health professionals as free samples. After arrival in the recipient country all donated drugs should have a remaining shelf-life of at least one year.
Presentation, packing, labeling	<ul style="list-style-type: none"> All drugs should be labeled in a language that is easily understood by health professionals in the recipient country; the label on each individual container should at least contain the International Nonproprietary Name (INN) or generic name, batch number, dosage form, strength, name of manufacturer, quantity in the container, storage conditions, and expiry date. As much as possible, donated drugs should be presented in larger quantity units and hospital packs. All drug donations should be packed in accordance with international shipping regulations, and be accompanied by a detailed packing list which specifies the contents of each numbered carton by INN, dosage form, quantity, batch number, expiry date, volume, weight and any special storage conditions. The weight per carton should not exceed 50 kilograms. Drugs should not be mixed with other supplies in the same carton.
Information and management	<ul style="list-style-type: none"> Recipients should be informed of all drug donations that are being considered, prepared or actually under way. In the recipient country the declared value of a drug donation should be based upon the wholesale price of its generic equivalent in the recipient country, or, if such information is not available, on the wholesale world-market price for its generic equivalent. Costs of international and local transport, warehousing, port clearance, and appropriate storage and handling should be paid by the donor agency, unless specifically agreed otherwise with the recipient in advance.

From World Health Organization. Guidelines for Drug Donations—Revised 1999 (Second edition). Available at: <http://www.who.int/medicines/library/par/who-edm-par-1999-4/who-edm-par-99-4.shtml>.

assessments were accomplished and purchases were organized within the country.³⁶ The kits are prepackaged (easing logistics), include suggested treatment schedules, and contain equipment and two drug lists (the “A” list has 25 drugs for use by minimally trained health workers, and the “B” list has 31 drugs for physician prescribing). The emergency health kit evolved after 1990 (updated in 1998), and it was requisitioned and used more than once within the same disaster, which prompted fears of dependency on international suppliers. To combat dependency on the kit, WHO promotes the development of country-specific emergency drug lists and supplies based on local disease patterns. Emergency health kits were designed for use during the emergency phase of drought, famine, or war. The kits were not recommended in acute-onset disasters, such as hurricanes or earthquakes (where there is assistance within 24 to 48 hours of the disaster and health needs widely vary); in situations in which the cost of transportation is more than the kit itself; and in countries that have a national emergency formulary. Even though the kit has proved useful, it is the drugs that it contains that make it valuable.³⁶

There have been other ideas and regulations put forth to help encourage good donation practices and eliminate the undesirable practice of drug dumping. The ideas are wide ranging but focus primarily on providing quality assurance monitoring and holding donors accused of dumping accountable for their actions.³⁸ Snell⁶ notes that donors and “relief agencies need to educate the public about donations and maintain a commitment to high standards of excellence through consultation with media, and policy makers.” Hillstrom²⁵ suggests allowing a donation to be used only for care of the ill, needy, or infants, and not to be transferred in exchange for money. Furthermore, donations should comply with WHO’s guidelines, include proper documentation, and be valued at reasonable market rates to prevent donations being made solely for tax deductions.^{25,39} Thomas¹⁹ recommends that any British pharmaceutical company taking a deduction in its tax bill for donations should list the donation in its annual accounts (published publicly). Thomas¹⁹ also suggests a change in the laws that would give the tax credit to the recipient country and not allow any donations that fall outside of WHO guidelines to qualify the donor for benefits. In 2002, Britain announced a series of measures that would ease access to essential medicines for many poor people living in developing countries. These measures include funding research into new treatments for the three “target” diseases identified by the UN (malaria, tuberculosis, and AIDS) as well as legislation encouraging donations of medicines by UK-based pharmaceutical companies.¹⁹ WHO recommends that donors pay attention to logistical issues, such as proper documentation, looking into applicable local laws, considering warehouse costs and weather, and obtaining better information from the recipient.¹ Other WHO suggestions include allocating resources at the beginning of an emergency situation for coordinating donations, creating collection centers, setting donation and national drug policies, and educating the public.^{1,39}

Blood Donations

Blood donations are “part of the altruistic response of the general public.”⁴⁰ After a disaster, people donate blood because of an awareness of the need for blood in the community, sense of social obligation or duty, personal social pressure, need to replace blood used by a friend or relative, and to increase self-esteem.⁴¹ These reasons seem to outweigh the reasons people do not donate, such as fear, inconvenience, perceived medical disqualification, being too busy, not being asked, and apathy.⁴¹

Staggering amounts of blood are donated after a disaster.⁴² Within 5 days after the 1989 San Francisco earthquakes, donations were up 200% from baseline (in affected and unaffected cities).⁴⁰ After the terrorist acts on Sept. 11, 2001, blood donations increased 1.3- to 2.5-fold. Mass appeal and blood drives led to the collection of 572,000 units, with enough blood collected by the second day to serve the situational needs. The overwhelming response included 12,000 phone calls (to blood banks) and 5000 units donated in 24 hours, 1800 units of blood escorted by police into the area, and the public lining up for hours and organizing themselves by blood type.⁴³ Although flights were grounded, the American Red Cross activated its aviation incident response team and mobilized 50,000 units of blood from around the country to be shipped by military transport.^{41,43}

Further reports from American Blood Centers (75 centers collecting half of the volunteer blood supply in the United States) noted that 259,000 people donated during the four days after the attacks (three times the normal level).⁴⁴ Also, the Red Cross reported 615,995 donations at 36 sites (two times the normal level).⁴⁴ So much blood was donated outside of hospitals that 208,000 units of blood were discarded in the weeks after Sept. 11 (five times the normal level), and in the end, only 206 units of blood were used for individuals injured in the attacks.⁴⁵

INTRODUCTION TO VOLUNTEERISM

Disaster Volunteerism

Volunteer numbers also surge after disasters. With proper management and direction, volunteers can accomplish a lot. Otherwise, they may hinder the response and become a logistical problem.²⁸ Some authors believe that “what the public does (individually and collectively), will make the biggest difference in the outcome of a disaster” and that volunteers can be integrated into the disaster response.^{46,47} Others note, however, that “freelancing” medical personnel and “convergent volunteerism” are system problems and disruptive to disaster management.^{46,48} *Convergent volunteerism* has been defined as the unexpected or uninvited arrival of personnel wishing to render aid at the scene, who then engage in freelancing (operating at an emergency incident scene without knowledge of the command authority).⁴⁸ Most volunteer convergence occurs for two reasons: first, officials overestimate the damage and issue requests from the scene to “send everything you’ve got,” and second, the immediate shortfall of official responders is filled by bystanders.

Certainly, most disasters can benefit from volunteers. Civilian volunteer organizations such as the Red Cross, Voluntary Organizations Active in Disasters (VOAD), and NYC Mayor's Voluntary Action Center allow people to get involved and be helpful where needed.⁴⁹ New York City has civilian volunteer managers who are experts in this field but were underused during the initial phases of the Sept. 11, 2001, terrorist attacks.⁴⁹ Aside from large civilian volunteer organizations, most volunteers in disasters take part because of timing, the situation, and a desire to help others. Spontaneous volunteers are particularly important for early search and rescue efforts. During the Nimitz Freeway collapse in the 1989 Loma Prieta, Calif., earthquake, 50 people were rescued—49 by bystanders. The volunteers fashioned backboards out of road signs, then waited hours for emergency medical services (EMS) to arrive.⁴⁷ Bystanders commonly conduct immediate uncoordinated search and rescue efforts (mostly during large, multisite disasters when EMS is disrupted) and will leave once they feel that EMS on-scene is adequate.^{46,47,50,51} Since bystanders and victims accomplish the most immediate search and rescue efforts, it seems wise to plan around this instead of completely discouraging it. Emergency responders can be trained to direct and coordinate these efforts, especially since it is the spontaneous volunteers who often know who is missing and where they were last seen. During the 1998 Swissair crash, local firefighters and fishermen were organized into search and rescue boat groups ("recovery volunteers"), while other local residents ("instrumental volunteers") performed supportive roles. Unfortunately, and not for lack of effort or organization, they found no survivors, but only wreckage and human remains. In addition, these volunteers were given inadequate support after the disaster (46% to 71% of volunteers suffered from posttraumatic stress disorder).⁵²

Nevertheless, volunteers can become a liability at disasters when they hinder logistics, cross roles, compromise safety and control, and do not follow proper incident command structure or medical oversight.⁵³ There are anecdotal stories from the Sept. 11, 2001, terrorist attacks of surgical medical students wearing scrubs and carrying sterile thoracotomy kits around the World Trade Center collapse zone. Clearly, though well intentioned, these types of efforts are ill conceived and have substantial risks with minimal benefits.⁴⁸ For example, a nurse who attempted to offer assistance without proper on-scene protective gear after the bombing of the Murrah Federal Building in Oklahoma City was killed by falling debris.⁵⁴

HISTORICAL PERSPECTIVE

Volunteerism

Volunteers have been referred to as the "silver lining" in the cloud of disaster and have been seen as heroes with a badge of honor. Feelings of patriotism, courageousness, spirituality, sense of duty, and even guilt compel people to volunteer.^{49,55,56} Volunteerism benefits the community as well as the individual donating his or her efforts by allowing the individual to do something "constructive and communal for his or her own mental health, as an outlet for

rage, and to overcome the sense of powerlessness."⁴⁹ Generally, volunteers tend to be people who believe in the good intentions and honesty of others and are agreeable, altruistic, and sympathetic.⁵⁷ Furthermore, in a study conducted by Elshaug,⁵⁷ volunteers were easy going, active, energetic, and able to concentrate on the task at hand.

Understanding the public's disaster response is important for realistic disaster planning.^{46,47} Studies of public behavior during disasters have shown that panic is extremely rare in these situations. Certain situations, though, such as being trapped in a burning building, can lead to panic (Coconut Grove nightclub fire of 1942), but again, this is rare. Extensive studies of more than 900 building fires (including the World Trade Center attacks in 1993 and 2001 and the Beverly Hill Supper Club Fire) failed to find any panic.^{58,59}

The role that volunteers play during a disaster is another issue. The literature deals primarily with convergent volunteerism by medical, fire, law enforcement, and civilian personnel.⁴⁸ Bissell⁵¹ put forth some general rules for individual roles in disaster situations, including that physician intervention should be at the triage area (except in entrapment situations), that only specially trained physicians and nurses should work in the field environment, and that a physician's primary role is at the hospital. Most physicians are not trained to work in austere environments, such as a California bus accident where on-scene volunteer physicians and nurses contributed to a chaotic scene by "performing poorly" (such as not knowing basic cardiopulmonary resuscitation).^{48,60} Physician roles can become even more confused when individuals with various academic training levels are on-scene (medical student, resident, attending), and most of the rescue personnel do not understand the differences between them or are not able to verify credentials. Medical personnel perform best when they do tasks similar to their day-to-day activities.^{28,54,61}

Convergent volunteers often tend to be viewed as an unwanted nuisance by disaster planners, whose conception of a disaster response often focuses exclusively on the activities of authorized agencies.⁴⁷ Some, for example, have complained that convergent volunteers create problems with protocol adherence, crowd control, security, safety, patient tracking, and liability and accountability and that they have to be given food, shelter, and sanitary facilities.^{48,62} However, field disaster research studies have shown that most initial search and rescue, casualty care, and transportation efforts in disasters is not carried out by police, fire, and EMS personnel according to a disaster plan; rather, these tasks are performed, on an ad hoc basis, by untrained citizens (family members, co-workers, neighbors, and persons who just happen to be in the area).^{47,63}

This often occurs because early in the disaster response there are not enough authorized and trained people available to do the job, when and where it needs to be done. In such a case, bystanders, the victims themselves, and other persons fill in the gap. Sometimes, some simple measures by the first arriving police, fire, or EMS units can help to guide and channel the efforts of bystander volunteers and make their efforts more effective. For example, after a tornado struck Waco, Texas, in 1953, initial search

and rescue efforts were uncoordinated and inefficient. However, military workers subsequently brought organization to the rescue efforts by incorporating civilian volunteers into their teams. Most of the teams were composed of 15 men under a leader and an assistant leader, along with another person carrying a walkie-talkie to keep in contact with headquarters and other nearby teams. Signs were put up showing each team's area of operation.⁶⁴ Disaster plans should include provisions indicating who is responsible for coordinating spontaneous volunteers working at the scene. Disaster training and drills should also address this responsibility.

Volunteer convergence at hospitals can lead to problems with safety and quality care.⁶⁵ Hospitals have to comply with Joint Commission of Accreditation of Healthcare Organization (JCAHO) standards for emergency credentialing of physicians and nurses. Acceptable sources of identification include a current picture hospital identification card, a current license to practice with proof of membership to a disaster medical team, or verification of the volunteer's identity by a current member of the hospital staff.⁶⁵ A volunteer's licensure and competency should be verified through a set process as well as shadowing a staff physician.⁶⁵

CURRENT PRACTICE

Volunteerism

The effectiveness of physician volunteers may be enhanced to the extent that they are integrated into a planned response (e.g., one coordinated by the local medical society, Metropolitan Medical Response System, or Medical Reserve Corps). Knowledge of the Incident Command System is also a useful asset.²⁸ This type of integration worked in the wake of the 1995 Murrah building bombing, the 1985 Mexico earthquake, the 1953 Waco tornado, and the 1994 Northridge, Calif., earthquake (where volunteering nurses were integrated into the Visiting Nurse Association through the local EMS agency).^{42,47,62,66} Physicians who become involved with patient care outside of the hospital should try not to deter EMS personnel from following their protocols unless there is a compelling reason to do so and after consulting with their base station physician, if that is possible.⁴⁸ Medical personnel should ignore overly hyped media reports and understand credible calls for help and the normal channels they go through.⁴⁶ On the other side, the government officials or news media that are calling for volunteers or donations should check with the intended recipients to see what kind of help is really needed. Furthermore, government officials should inform the news media proactively when volunteers or donations are not needed.⁴⁷

Various guides, such as those produced by the states of California and Florida, discuss ways of handling volunteer convergence among the public.^{67,68} Some authors report that the public is "treated as an unwanted nuisance by professionals" and the yellow tape perimeter acts as physical and psychological barrier.⁴⁷ Instead of pushing the public into a secondary role, Glass⁴⁷ suggests

getting the public involved through announcements, forming partnerships, and mobilizing local organizations. Since it is a virtual certainty that untrained members of the public will become involved in casualty care in widespread disasters, it is important to provide them with information on how they can protect themselves and help others. This can be done before an event and can be supplemented with real-time information during a disaster. Examples include how to shelter-in-place; how to decontaminate exposed persons; how to shut off gas and electricity; where to obtain antidotes, potassium iodide, or prophylactic antibiotics; and what hospitals and medical facilities are open, the least crowded, and where they are located.

Furthermore, disaster personnel should enlist the media as an ally, as was done during hurricane Andrew and a Homestead, Fla., area AM radio announcer who was credited with saving many lives by instructing people to get into their bathtubs and cover themselves with mattresses.⁴⁷ Also, it is important to educate volunteers, perform community-wide rapid needs assessment, set up statewide medical mutual aid radio systems, and announce what type of donations and volunteers are needed.⁴⁶ JCAHO recommends promoting community emergency preparedness plans. This comprises enlisting the community in local response preparations, encouraging an emergency preparedness focus, developing emergency planning and preparedness templates, preserving local healthcare, and establishing leadership and sustainment guidelines.⁶⁹

Personal Protective Equipment

John L. Hick and Craig D. Thorne

Personal protective equipment (PPE) recently has become a rather common acronym in the lexicon of healthcare providers, even though it has been common in the fire services, emergency medical services (EMS), and military for quite some time. Essentially, PPE helps ensure that individuals are safe from physical hazards that they may encounter in their work environment. PPE may be used to protect workers from general environmental threats (e.g., temperature extremes, noise), specific work-related threats (e.g., falling objects, falls from heights), or threats faced in an emergency situation (e.g., hazardous chemical and infectious agents). No equipment is appropriate for all individuals and threats, but it must be selected and properly used according to the setting of use and the level of risk.

The critical problem with most PPE, particularly in regard to chemically protective suits and respirators, is that with higher levels of protection come not only higher prices and required training levels, but also a higher physiological and physical burden to the user. Thus, a structured approach to assessment of risk and selection of proper equipment is important to achieve a reasonable level of protection in relation to the hazard.

This chapter reviews the concepts of PPE, recent lessons learned in regard to PPE, types of respirators, key regulations, and issues in the selection of PPE for emergency medical care and decontamination operations.

HISTORICAL PERSPECTIVE

Until recently, PPE for medical providers received little attention short of the “standard precautions” of gloves, with the addition of simple masks and barrier precautions, when needed. The 2003 severe acute respiratory syndrome (SARS) pandemic, the 1995 Tokyo subway sarin attack, the 1995 Murrah Federal Building bombing in Oklahoma City, and the terrorist attacks of September 2001 are some examples of situations in which the lack of proper PPE resulted in adverse health effects for healthcare providers and thus focused attention on PPE as a critical issue in disaster response.

In March 1995, a crude form of the nerve agent sarin was released in the Tokyo subway system on separate cars bound for a common downtown station. This attack

resulted in 12 deaths and more than 4000 persons presenting to the hospital for medical evaluation. None of the casualties was decontaminated before treatment or transport. Retrospectively, 135 prehospital and 100 hospital personnel reported symptoms consistent with nerve agent exposure. Fortunately, none required emergency treatment.^{1,2} Eleven physicians caring for the sick-est victims (including one in cardiac arrest and one in respiratory arrest) were most affected, and six of them required antidotal therapy. Fortunately, all recovered fully and did not have to cease their patient care efforts due to symptoms.³ Approximately 80% of victims self-referred to hospitals, which is consistent with U.S. experiences indicating that few victims of chemical contamination events undergo decontamination before arrival at a medical facility.^{2,4} This has caused most jurisdictions to reconsider historical plans that contaminated patients would not be in contact with medical care personnel until they were “clean.” EMS and hospital personnel need to be prepared for contaminated patients presenting directly to them and to recognize that in certain situations, PPE may be required to safely provide care.

SARS posed unique risks and challenges to healthcare workers. This novel viral agent with incompletely defined transmission characteristics was controlled in 2002 with aggressive quarantine measures and use of PPE. In the first wave of SARS in Toronto, 79.2% of all cases were acquired in a healthcare setting.⁵ Aggressive use of PPE, including N95 masks, barrier precautions, and gloves, was generally effective at preventing spread, although during one difficult and prolonged intubation attempt, at least six providers contracted SARS from a patient despite complying with PPE recommendations.⁶ This case led to recommendations that higher levels of PPE may be required during procedures that are likely to generate aerosols or provoke coughing, such as intubation, airway suctioning, positive pressure ventilation, and nebulization treatments.⁷

The National Institute for Occupational Safety and Health (NIOSH) and the RAND Corporation produced a comprehensive “lessons learned” report summarizing issues from the 2001 terrorist bombings at the World Trade Center (WTC), anthrax incidents, and the 1995 Oklahoma City Murrah Federal Building bombing. The report, titled “Protecting Emergency Responders: Lessons

Learned from Terrorist Attacks” describes in detail many of the challenges responders faced (Box 36-1).⁸

It is clear from the WTC events that a large number of jurisdictions responding, conflicting messages regarding use of PPE and safety of the environment, and lack of a plan to implement respiratory precautions can complicate a response and potentially place providers at risk. WTC responders continue to suffer respiratory symptoms attributable to exposures at “ground zero.”⁹

CURRENT PRACTICE

Hazard Vulnerability Analysis

Selection of appropriate PPE begins with an analysis of the hazards that responders may encounter and an assessment of responders’ roles and responsibilities. Hazard vulnerability analyses (HVA) are required for community emergency planning grants and are required of healthcare facilities that are accredited by the Joint Commission on Accreditation of Healthcare Organizations (JCAHO).¹⁰ The HVA uses a numerical ranking of factors for specific threats (e.g., chemical release), including the risk of the event occurring, the current preparedness for the threat, and the risk to life. The numerical score determines the gravity of each threat to the community. Each community’s HVA will reflect the unique risks that must be considered by its emergency responders. Choice of PPE may be affected by factors within the HVA such as:

- Population density of the community and surrounding area
- High- or moderate-risk terrorist targets in the community (e.g., government buildings, centers of commerce, or another symbolic site)
- Chemical hazards posed by community industry (e.g., use of cyanide and hydrofluoric acid in the electronics industry)
- Risk of transportation incidents and major transportation routes, particularly highways and railroads
- Proximity of healthcare facilities, schools, or other key locations to these potential targets and industrial and transportation hazards
- Frequency of hazardous materials (HazMat) incidents in the community
- Resources available to respond to HazMat incidents (e.g., rapid access to on-site decontamination may decrease, but not eliminate, contaminated persons leaving the scene)

Defining the Agency/Facility Role

Stakeholders in emergency response, including EMS and healthcare facilities and fire and rescue, emergency management, and law enforcement agencies, must clearly define the responsibilities of each entity and the support and resources that each may need or offer during an emergency, particularly one involving a HazMat release.

EMS roles in a HazMat event vary depending on jurisdictional planning. Fire services personnel may or may

BOX 36-1 HISTORICAL HAZARDS FACED BY RESPONDERS TO TERRORISM EVENTS

- Physical hazards including fires, burning jet fuel and explosions, rubble piles with sharp rebar and heated metal, falling debris (which resulted in the death of a nurse in Oklahoma City), hazardous materials, electrical hazards, structures prone to collapse, heat stress, exhaustion, and respiratory irritants
- Heat-related seizures while wearing chemically protective suits
- Eye injuries (usually related to particulate exposure), which accounted for 12% of all WTC disaster response worker injuries
- Potential for secondary hazards, including explosive devices and chemical, biological, and radioactive agents
- PPE shortcomings:
 - Heavy helmets hindered performance
 - Self-contained breathing apparatus (SCBA) was heavy and cumbersome
 - SCBA face pieces fogged (reducing visibility), and the equipment hindered verbal and radio communication
 - SCBA air bottle made it difficult to enter small spaces, and the limited air supply (up to 1 hour) necessitated leaving the operation to exchange the air bottle
 - Air tanks and/or filters were not interchangeable between teams, and teams worked under different standards
 - Powered air-purifying respirator (PAPR) filters became clogged and were uncomfortable for long duration use. Many workers instead opted to use dust masks (which offered little protection and caused nose-bridge chafing) or to wear the masks/hoods around their necks (“neck protectors”)
 - Use of respirators made it difficult for workers to communicate with each other, often resulting in users breaking the face seal to talk
 - Turnout gear (the common protective garments used by firefighters) increased heat stress and physical fatigue
 - At the WTC, the rubble pile was so hot in places that it melted the soles of workers’ boots; providing wash stations to cool the boots resulted in wet feet and serious blisters for many workers; some 440 WTC disaster response workers sought treatment for blisters
 - Steel-reinforced boots (soles and toes) protected against punctures by sharp objects but conducted and retained heat, which contributed to blisters and burns
 - Structural firefighting gloves worked well until they got wet and hardened, reducing their dexterity
 - WTC disaster response workers did not consistently protect their hands against potential hazards such as human remains and bodily fluids
 - Safety glasses were readily available but often were open at the sides and did not offer adequate protection against airborne particles
 - Goggles were uncomfortable, hindered peripheral vision, tended to fog, and did not fit well in conjunction with half-face respirators
 - Many disaster response workers at the WTC (especially law enforcement officers) did not consistently use hearing protection, even around heavy machinery, because they needed to hear their radios and voices and listen for tapping when they were searching for survivors
- Most volunteers at the WTC, Pentagon, and Oklahoma City did not receive pre-event training on PPE and hazardous materials
- Although firefighters generally received detailed pre-event training, this was less true for law enforcement officers
- Accurate “real-time” hazard information was not readily available, especially during the anthrax incidents
- Protection from falls was available at some sites (in the form of ropes and harnesses) but was inconsistently used

not be able to provide treatment in a “warm zone” (i.e., the area of reduced contamination outside of the immediate release zone) depending on their training. Non-fire based EMS personnel may require PPE to triage and treat victims in the warm zone. In the event of a mass chemical exposure, victims will likely self-refer to visible ambulances, call 911 from sites removed from the site of release, or make their way to hospitals, by-passing organized EMS and fire services. This movement of contamination on the bodies of patients essentially causes a “migrating” warm zone, causing contamination of previously clean (“cold”) areas. This migrating contamination may require protective equipment for EMS responders, and appropriate plans and equipment should be in place. The roles and responsibilities of the responders, as well as the equipment required, need to be defined and drilled in advance of an incident.

Hospitals, until very recently, usually relied on fire services for patient decontamination at the hospital. These resources, however, are often deployed to the scene of the event and are thus unavailable to support the hospital. Most hospitals have now recognized the need for at least some internal capacity for patient decontamination and are equipping their teams with PPE appropriate for decontaminating self-referred contaminated patients. A few hospital teams integrate with community HazMat teams, necessitating additional training and equipment as the mission then changes from a defensive decontamination response to an offensive response at the scene of release.

Risks to Providers

HazMat releases seldom cause serious injury, but the potential exists for both scene responders and hospital receivers to suffer serious consequences of exposure. The Agency for Toxic Substance and Disease Registry (ATSDR) maintains a multistate voluntary accounting of hazardous substance releases, excluding petroleum-related incidents. The Hazardous Substances Emergency Events Surveillance (HSEES) database currently involves 15 states.¹¹ From 1993 to 2001, 44,015 events were recorded: 3455 (7.8%) of the incidents caused injuries, and 74% of victims were transported to a healthcare facility.⁴ In another analysis of HSEES data, only 5% of victims required admission to a healthcare facility.¹² The vast majority had self-limited respiratory symptoms. In 2001, the chemicals with highest potential for injury were chlorine (injury occurred in 18.8% of releases), ammonia (18.2%), acids (14.2%), and pesticides (17%).¹³

HSEES data from 1996 to 1998 show 348 responder injuries in 126 incidents out of a total of 16,986 incidents (0.7%). Law enforcement officers and firefighters accounted for the vast majority of responder injuries, which usually consisted of nausea and respiratory irritation. Hospital admission occurred in 6.6% of cases. No deaths were reported in this 3-year period.⁴

Hospital personnel were injured in 0.3% of the total HazMat events and represented 0.1% of the victims.⁴ Six events involved emergency department staff contact with contaminated patients, and five events were HazMat releases at the healthcare facility itself. No provider required hospital admission, and no chemical PPE was

used. Other reports of emergency department evacuation and/or provider illness due to off-gassing from contaminated patients have been summarized.¹⁴⁻¹⁹ The most serious of these incidents involve patients with suicidal ingestions of organophosphate pesticides.¹⁴⁻¹⁶ Exposures to these patients caused at least one provider to require intubation and receive aggressive antidotal therapy due to contact with pesticide in emesis and vapors during patient resuscitation.¹⁴ Patients who have ingested organophosphate may off-gas for days and present an ongoing risk to healthcare workers.¹⁶ NIOSH has documented 46 healthcare worker injuries from pesticide agents between 1987 and 1998.¹⁴ In conjunction with the information from the Tokyo subway sarin attack and the chemical terrorism risk posed by these agents, it is clear that these pesticides present a substantial risk of toxicity from secondary exposures.

Limited research is available to document the degree of the off-gassing that occurs from the bodies and clothing of contaminated patients.^{20,21} Clothing removal and control may be expected to remove 90% of the contaminant and thus should be a priority.^{21,22} Ideally, this should take place in an open-air environment.

Chemical Protective Equipment

Providers may not initially recognize a chemical release when they arrive at a scene. Even though structural firefighting ensembles with self-contained breathing apparatus (SCBA) offer some chemical protection that may be sufficient for victim rescue,²³ the incident commander must determine what actions are appropriate for the situation. Protective suits, gloves, and boots and appropriate respiratory protection must be donned as soon as possible when a chemical threat is recognized.

The Occupational Safety and Health Administration (OSHA) and Environmental Protection Agency define four basic levels of PPE for HazMat scene responses (Table 36-1 and Fig. 36-1) (OSHA standard 29 CFR 1910.120, Appendix B). Generally, as the level of protection increases (A being the highest level), so do the weight, cost, and physiological burden. Increasing protection also generally means decreasing mobility, dexterity, and scope of vision. Inherent risks to PPE include trip and fall hazards; a reduced ability to complete tasks; heat stress^{19,24-27}; anxiety²⁸; and seizures, which, although rare, have been reported.¹⁹ Cardiovascular demand is dramatically increased as ensemble weight and heat retention increase. PPE must be selected on the basis that it does not impose unnecessary risks on the provider while at the same time offering an appropriate margin of safety against the chemical hazard. Because the selection of PPE usually revolves around the selection of the respiratory component, various types of respirators must be reviewed. Each respirator has an assigned protection factor that reflects the degree of protection afforded to the user. Simply put, 1/protection factor equals the amount of exposure for the wearer. For example, a provider wearing a powered air-purifying respirator (PAPR) with an assigned protection factor (APF) of 1000 is exposed to 1/1000 the level of contaminant as compared with wearing no protection.

TABLE 36-1 CATEGORIES OF PPE

LEVEL	BRIEF DESCRIPTION	ADVANTAGES	DISADVANTAGES
A	Completely encapsulated suit and SCBA	Highest level of protection available for both contact and vapor hazards	<ul style="list-style-type: none"> • Expense and training requirements typically restrict use to HazMat response teams • Lack of mobility • Heat and physical stresses • Limited air supply • Fit-testing requirements
B	Encapsulating suit or junctions/seams sealed, and supplied-air respirator (SAR) or SCBA	High level of protection adequate for entry into unknown environments	<ul style="list-style-type: none"> • Same as for Level A • SAR hose may pose a trip hazard or become dislodged
C	Splash suit and air-purifying respirator (APR) (note APR and PAPR considered equivalent in classification despite significant difference in protection)	<ul style="list-style-type: none"> • Significantly increased mobility • Less physical stress • Extended operation time with high levels of protection against certain chemical hazards • No fit-testing required for hood type 	<ul style="list-style-type: none"> • Not adequate for some high-concentration environments, less-than-atmospheric-oxygen environments, or high levels of splash contamination
D	Usual work clothes	<ul style="list-style-type: none"> • Increased mobility • Less physical stress • Extended operation time • More fashionable 	<ul style="list-style-type: none"> • Expense and training moderate • Offer no protection against specific hazards • Expense and training minimal

Atmosphere-Supplying Respirators

Atmosphere-supplying respirators provide breathable fresh air to the user *independent of the environment* via an air supply hose and/or tank and thus offer a high level of respiratory protection. This type of respirator is required for entry into environments where the identity of and/or the potential quantity of a hazardous substance are unknown or where the quantity of oxygen in the air is unknown.

SCBA is the most common atmosphere-supplying respirator for emergency responses. It provides air via a tank, usually worn on the back. The operational time is limited by the capacity of the tank (usually less than 1 hour). Fire services personnel routinely use this form of respiratory protection, and fire-based EMS services personnel generally incorporate this PPE into their chemical protection planning. Limitations include the equipment’s weight (approximately 25 to 30 pounds), cost, need for fit-testing, duration of air supply, and need to refill air bottles. Even though SCBA provides excellent protection, its limitations make it inappropriate for many situations (e.g., caring for a patient with an infectious disease, providing hospital-based decontamination, or securing a perimeter in the warm zone). SCBA has an APF of about 10,000, the highest of any type of respirator.²⁹

Supplied-air respirators (SARs) provide air via a hose line from a nearby clean air source (e.g., compressor or hospital supply line). To meet OSHA requirements for level B, respirators must have a tight-fitting face piece and an emergency supply of air in case of line failure or problems.³⁰ Loose-fitting hoods with a supplied air source do not meet level B standards but are used by some decontamination teams when an additional level of protection is desired due to institutional preference or local hazard profile. Advantages include a potentially unlimited supply of fresh air and longer duration of use. Limitations are primarily mobility and thus flexibility of response. These respirators are best suited to healthcare

provider use in a decontamination room or a well-defined area in which the air lines are unlikely to be tangled, stretched, or a tripped hazard. The APF of a typical tight-fitting face piece SAR is 1000, although there may be variability among models and types (e.g., tight-fitting mask versus loose-fitting hood).²⁹

Air-Purifying Respirators

Air-purifying respirators (APRs) have cartridges that filter the air *in the user’s environment* to remove particulate matter and specific chemicals that the filter is designed to capture. These filters do *not* affect the oxygen concentration of the ambient air and thus cannot be used in potentially oxygen-deficient environments. Only those chemicals for which the filter is designated are removed. Also, the capacity of the filter can be exceeded by large amounts of contaminant, thus these respirators are designed for situations in which the concentration of the agent is either established to be or assumed to be below the threshold for the canister.

Nonpowered APRs use the wearer’s work of breathing to pull ambient air through the filter. Examples include dust masks and military and civilian “gas masks.” The APF of a nonpowered full face piece APR is 50 when appropriate *quantitative* fit-testing is performed.²⁹ Of note, this type of mask is used by the military for battlefield protection against lethal levels of nerve and other chemical agents. Advantages include low cost and long duration of use. Disadvantages include increased work of breathing and physiological stress, mask fogging, and the need for fit-testing.

A PAPR uses a motor to pull air through the filter canisters, thus decreasing the work of breathing and the risk of air entrainment around the respirator face piece. PAPRs are often supplied with a loose-fitting disposable or reusable hood that eliminates the need to perform fit-testing and allows use by a broad range of individuals. Hooded PAPRs with “stacked” canisters that offer protection against com-

FIGURE 36-1. Levels of PPE. (From Agency for Toxic Substances and Disease Registry. Emergency Medical Services Response to Hazardous Materials Incidents. Available at: <http://www.atsdr.cdc.gov/mhmi-v1-2.pdf>.)

mon hazardous chemical and biological agents encountered by first responders and hospital personnel are in widespread use due to their relatively low cost, weight, and the increased flexibility of response allowed. Dependence on battery power, shelf life of the filters, and the need to be able to match the filter to the agent are limiting factors. The currently proposed APF for a PAPR is 1000.²⁹ Directions for use must be carefully followed; one particular model provides a protection factor of 20,000 when properly donned, but when the inner hood is not tucked in, the protection level declines to 1000 and less^{31,32} (personal communication, 2001). Battery packs are usually either single-use or rechargeable. Rechargeable battery packs require ongoing attention to ensure a proper charge, but they offer the flexibility of allowing PAPR re-use during an infectious disease event.

Particulate filter masks such as those commonly used for patient care to protect against tuberculosis and other organisms are also considered APRs. Masks are classified N (not oil resistant), R (oil resistant), and P (oil proof). N95 refers to a filter (the entire mask) that removes 95% of a particulate challenge in the 3- to 5- μ m range. N100 respirators filter 100% of the same challenge, yet simple half-face respirators offer an APF of only 10 due to the entrainment of air around the mask and other factors; therefore, changing from an N95 to an N100 offers little additional protection unless a more robust mask ensemble, rather than a simple half-face mask, is used.^{33,34}

Respiratory protection technologies are rapidly evolving, and respiratory program administrators should make sure they are familiar with the available options and their relative advantages/disadvantages. Regional cooperative

planning and purchases may be helpful to allow for sharing of resources during an incident.

Chemically protective suits must be tailored to the type of use. Suits for hot zone entry where direct contact with a hazardous material is likely must be much more robust than suits for patient decontamination activities. Selection should be guided by National Fire Protection Association (NFPA) standards 1992 and 1994 for site-of-release response activities and by recent OSHA guidance for hospital decontamination activities.^{35,36} Chemicals commonly found in local transit, agriculture, or industrial use should also guide selection. Appropriate PPE for perimeter control and EMS warm zone operations remain topics of debate at this time. Generally, suits should be sized far more generously than standard work clothing to prevent tearing during squatting and other activities (e.g., an average 70-kg man should plan to wear a size XXL suit). Many suit configurations are possible, and the optimal configuration will depend on the mission and other equipment in the ensemble. For example, suits without “feet” are preferred when worn with boots (to allow taping over the boot) but those with integrated bootie “feet” are preferred when pull-on “sock” type butyl booties are to be used. These integrated feet should *not* be used as primary footwear at any time because they have poor abrasion resistance.

Boots supplied in sizes medium, large, and extra large rather than fitted sizes may be preferred when equipment is purchased for a group (e.g., hospital decontamination team) rather than being purchased for an individual responder (e.g., firefighter). Butyl or other rubber boots probably afford appropriate protection for warm zone operations. Butyl “sock” type booties may be used on very low abrasion surfaces (e.g., internal hospital decontamination room) but are not generally appropriate for outside use.

Nitrile overgloves with butyl overgloves provide protection against a broad range of hazards for warm zone activities. Silver Shield gloves are more expensive but may be better suited for particular compounds when the agent is known. Overglove selection should balance the need for abrasion resistance with dexterity required to perform tasks (e.g., to administer intramuscular antidotes). The U.S. Army Center for Health Promotion and Preventive Medicine (USACHPPM) recommends 14-mm thickness butyl gloves (standard examination gloves are 4 mm) as a minimum for working with patients contaminated by chemical warfare agents or toxic industrial chemicals.³⁷

Biological Protective Equipment

Very few situations require physical decontamination of patients exposed to biological agents. An exception would be patients who present after contamination with biological agents (e.g., anthrax spores) from a dissemination device. PPE for decontamination should consist of the same chemical protective suit and high level of respiratory protection, including a high-efficiency particulate (HEPA) or SAR, that would be used for chemical decontamination activities. PPE for biological agents

in relation to care of patients who are already infected and symptomatic is discussed in the following.

Categories of PPE for biological agents include³⁸:

1. *Standard precautions*: Use of gloves and proper hand hygiene to prevent disease transmission for any potentially infectious patient. Gowns and eye protection are added only when patient care activities are likely to result in splashing or soiling.
2. *Contact precautions*: Standard precautions *plus* use of barriers during *all* patient care activities to protect face, arms, and front torso to prevent contact with secretions, emesis, feces, etc. (e.g., enteric infections, many hemorrhagic fever viruses).
3. *Droplet precautions*: Standard precautions with the addition of a droplet respirator (e.g., surgical mask) when working within 3 feet of the patient to prevent transmission of infectious agents that travel by large droplet spread (e.g., airborne precautions are used against plague); may not be protective against all droplet nuclei.
4. *Airborne precautions*: Standard precautions with an N95 or higher protection respirator to prevent transmission of infectious agents that are spread by aerosols (e.g., airborne precautions are used against chickenpox, smallpox, and tuberculosis).
5. *“Special pathogen precautions”*: Based on the SARS experiences, a high-risk pathogen with respiratory spread probably requires greater levels of protection than previously recommended. Constant use of both contact and airborne precautions has generally been advised with the optional use of a PAPR rather than an N95 mask during “high-risk” interventions likely to generate aerosols or provoke coughing (e.g., suctioning, intubation, positive pressure ventilation).^{6,7} These precautions are the subject of current discussion.

Patient care providers should have routine access to nonsterile examination gloves, barrier gowns that protect the arms and front torso, standard surgical (droplet) masks, and a face shield that provides adequate splash protection (which may be integrated with the mask, a separate face shield, or goggles) according to the OSHA bloodborne pathogens standard.³⁹

Providers should have ready access to higher levels of protection when needed. “Bad bug bags” may be assembled with appropriate gowns, gloves, face shields/goggles, N95 or PAPR respirators, and other supplies so that healthcare providers do not have to assemble the recommended components. Instruction sheets for donning/doffing and disinfection procedures can be included in the bag.⁴⁰

Practitioners fitted for N95 respirators may use these for patient care, and others should have access to a PAPR until they are fitted for an N95 respirator. Plans to rapidly fit-test additional employees during an event that might require prolonged use of airborne precautions (e.g., SARS) should be in place.

Regulations and Training

All PPE must be part of an ongoing program of respiratory protection and HazMat/decontamination response within the agency or institution to ensure that employees who are

expected to use these protections are competent and comfortable with the indications, use, and limitations of their equipment. Numerous regulations apply to the selection and proper use of PPE. All persons using PPE must conform to OSHA standards on respiratory protection (29 CFR 1910.134), PPE (29 CFR 1910.132), eye and face protection (29 CFR 1910.133), hand protection (29 CFR 1910.138), hazard communication (29 CFR 1910.1200), and blood-borne pathogens (29 CFR 1910.1030). State OSHA agencies may have stricter requirements than the federal standards. Most occupational or employee health services of agencies/facilities where PPE is used are very familiar with these standards and their application to employees.

The NFPA has numerous standards for the training and equipping of responders (including EMS personnel) to a HazMat incident (e.g., NFPA standards 471, 473, 1981, 1992, 1994, and 1999). Specific guidance is also provided for urban search and rescue teams (NFPA standard 1951).³⁵ Responders to HazMat releases are covered by OSHA's HAZWOPER (Hazardous Waste Operations and Emergency Response) standard 29 CFR 1910.120, which is perhaps the most comprehensive standard guiding hazardous materials responses.

OSHA requires use of a minimum of level B equipment (i.e., an atmosphere-supplying respirator and chemically protective suit with sealed seams) during a response into a contaminated environment until the concentration of the agent is shown via air monitoring to be below the threshold required for the safe use of an APR or other lesser degree of protection.⁴¹ This requirement presents difficulty for EMS and hospital providers because the agent is often unknown at the time that medical care is provided in the warm zone (i.e., an area where the level of contamination is minimal and controlled). Particularly for hospitals, confusion existed as to what constituted appropriate protection for decontamination team members who provide medical care for contaminated patients and to what degree the HAZWOPER standard applied to community responders geographically separate from the site of release.

OSHA clarified this issue for healthcare facility providers in two letters of interpretation^{42,43} and a comprehensive guidance document on PPE and training released in 2004.³⁶ In this document, OSHA codifies use of PAPRs as the minimum level of respiratory protective equipment for hospitals under certain conditions:

- The facility acts as a "first receiver" for self-referred contaminated casualties, *not* as a responder to a release zone.
- The facility itself is not the site of the hazardous substances release.
- An HVA has been conducted to identify specific hazards to the community and facility.
- The victims must present at least 10 minutes after exposure (to allow time for some of the contaminant to evaporate or dissipate). It will usually take at least this long to get personnel into PPE at the facility.
- The victims' clothing must be rapidly removed and contained.
- Decontamination must occur in a well-ventilated area, preferably outdoors.

When these conditions are met, and absent any particular threats within the community that require higher levels of protection (such as close proximity to a specific chemical production, storage, or disposal site), the minimum level of respiratory PPE is a PAPR with a protection factor of 1000 or greater, which filters organic vapor, acid gas, particulate matter, and biological agents (at the HEPA level).³⁶

HAZWOPER also defines training requirements for responders.⁴⁴ The application of these regulations to hospital decontamination teams was also clarified in recent OSHA guidance.³⁶ Awareness training is required for individuals involved in a HazMat response who will not be using PPE or taking actions beyond recognizing and reporting an incident (emergency department staff, law enforcement officers).⁴³

At a minimum, all responders who will use chemical PPE must be trained to the operations level (8 hours or to competency)⁴³ so that each responder can:

- Understand his or her role in the response and the emergency response plan.
- Identify the presence of a hazardous substance through signs and symptoms of exposure.
- Assess site safety, including risks to self.
- Select and safely use appropriate PPE.
- Understand decontamination procedures.

HazMat awareness educational competencies must also be met by providers trained to the operations level. The awareness competencies may be included in the 8 hours of operations training or conducted separately.³⁶

In addition, any personnel using respiratory protective equipment must be in compliance with OSHA's respiratory protection standard (29 CFR 120.134). Key features of this standard are:

- Respirator selection procedures.
- Proper use of respirators in routine and reasonably foreseeable emergency situations.
- Medical clearance before use (at minimum, a screening questionnaire; see Appendix C of the standard).
- Fit-testing before use and annually thereafter (see Appendix A and B1 of the standard).
- Inspecting, cleaning/disinfecting, storing, repairing, and maintaining the equipment.
- Training and education on topics such as the types of respiratory hazards they might be exposed to, proper use (including donning and doffing), limitations, and maintenance.

Most medical facilities and response agencies have a respiratory protection program in place. This existing foundation and the subject matter experts in occupational safety and health, infection control, or other related disciplines can assist with implementation of new technologies and protocols.

PITFALLS AND ONGOING CHALLENGES

PPE technology continues to change rapidly. Hopefully, technologies that are lighter weight, less expensive, and less heat-retaining can be developed. Technology

change is occurring far more rapidly than the current approvals process and new standards that have arisen in the wake of the events of 2001. Clear guidance on appropriate technologies for warm zone activities is lacking at this time. This can lead to confusion and difficult choices for agencies and facilities, knowing that their PPE selection may be either too much or too little to satisfy future standards. Currently, there is no recommendation or consensus on the level of PPE that is required for hospital-based personnel, much to the consternation of hospital preparedness leaders. Some have proposed a PPE level "H" to meet this need. More research is clearly needed regarding safe but comfortable PPE, methods of decontamination, modeling of airborne concentrations of specific agents, and PPE selection.

Further, detection technologies are needed that can provide better environmental screening for a wide range of hazardous substances and quantitative assessment of agent concentration. Currently, incident commanders may remain confused about appropriate PPE, and this may result in PPE selection that is overly conservative (which risks provider noncompliance and adverse effects from the PPE) or overly liberal (which risks provider injury from the contaminant).

Finally, providers need to be educated about the consequences of not using PPE appropriately, including acute chemical effects and delayed pulmonary effects.

In general, communities and regions can help to reduce issues of PPE interoperability by planning, purchasing, and training together whenever possible. This also allows for caches of materials to be deployed that are true replacements for usual materials and thus will be better accepted and require minimal training.

For too long, jurisdictions have been reluctant to share their problems, issues, and roadblocks in the area of PPE, lest the agency be seen as having problems protecting its responders. Better dialogue and sharing of best practices and lessons learned are of immense value to better HazMat response planning and should be encouraged. The recent NIOSH/RAND report⁸ and release of select after-action reports are welcome changes in this history.

Defining hazards in this age of potential chemical terrorism is fraught with peril because we are unable to truly assess the scope of the threat. Thus, PPE must be chosen that will protect appropriately against a broad range of threats without being so restrictive that in the heat of the moment, the provider decides to forgo the PPE and is at risk of becoming a casualty of the event. Balancing cost, ease of use, and scope of protection concerns are delicate decisions with few answers at this time, particularly for those who may have long-duration job tasks in a warm zone environment.

We can only hope that we are not forced to learn too many more harsh lessons about PPE use in the future. In the meantime, however, we should strive to prepare our communities by selecting appropriate protective technologies in relation to perceived threats and practicing our responses so that our personnel are comfortable using their PPE and understand the consequences of not doing so.

Surveillance

P. Gregg Greenough and Frederick M. Burkle, Jr.

The World Health Organization (WHO) defines *surveillance* as “the ongoing systematic collection, analysis, and interpretation of data in order to plan, implement and evaluate public health interventions.”¹ The key elements are its continuous nature and its linkage to particular actions. Surveillance is repetitive, ongoing, and tied to operational activity and action-oriented policy, unlike rapid assessments and field surveys, which occur sporadically during a disaster by disparate organizations and institutions and provide a “snapshot” of a particular health issue because they are “one-off” type events. As the emergency phase of a disaster transitions into rehabilitation and development, surveillance data provide a trend analysis to detect successes or failures in policy, programming, and disaster management.

Surveillance also encompasses the “comparison and interpretation of data in order to detect possible changes in the health and environmental status of populations.”² Data collected and collated as the result of an event undergo timely analysis, interpretation, and distribution to all parties involved in the response and who have a stake in improving the population’s health. Thus, surveillance is a cyclical exercise that moves forward in time.³ In so doing, surveillance tracks the burden of disease on healthcare systems, identifies continuing health problems, and monitors the response to specific interventions. No other means of tracking health trends has this capability during a disaster.

HISTORICAL PERSPECTIVE

Historically, surveillance has been practiced in some form during the development of public health in the Western world. Beginning in the 17th century, Leiniz in Germany and Graunt in England advanced the notion of applying numerical value to disease and death counts. At the same time, Sydenham developed a classification for diseases on which a uniform understanding of its statistical analysis could be understood. By the 19th century, efforts were being made to nationalize health information, collect vital statistics, perform analysis, and initiate a reporting mechanism. In particular, the work of Farr in England and Shattuck in Massachusetts advanced these concepts, applying them to socioeco-

omic conditions and public health practice. By the turn of the century, all states and most European countries required reporting of specific infectious diseases. In the United States, the great influenza pandemic of 1918-1919 prompted a national mortality reporting requirement.⁴

Events during the 1950s and 1960s helped define the term surveillance and elucidate its role in public health practice. Langmuir at the U.S. Centers for Disease Control and Prevention (CDC) emphasized the systematic collection of pertinent data and its timely analysis and dissemination to policy makers; Raska at WHO stressed that surveillance should apply to prevention as well as control of communicable diseases. In 1968, the World Health Assembly broadened the role of surveillance beyond the realm of communicable diseases. Since then, surveillance has been applied to lead poisoning, injury, drug abuse, congenital malformations, behavioral risk factors, and disasters, as well as many other public health issues.

The routine use of surveillance in humanitarian relief emerged with the development of standards for field operations. Before the 1990s, the profession of humanitarian relief, with its wide range of agencies working at all levels of capacity and often with poorly trained workers and volunteers, was not held accountable for its own work. In 1996, a group of experts from 228 humanitarian organizations began fashioning minimum technical and ethical standards in all sectors—food, nutrition, water, sanitation, and health services. Titled the Sphere Project, it has become the consensus opinion on how humanitarian professionals should operate during conflicts and disasters. According to Sphere, the design and development of health services should be “guided by the ongoing coordinated collection, analysis and utilization of relevant public health data.”⁵

Perhaps the most poignant example of the use of surveillance and its immediate ramifications took place in Goma, Zaire, in 1994. Weeks after a sudden massive movement of refugees went to Goma, a land ill-equipped to sustain them and where public health infrastructure was lacking, an epidemic of cholera resulted that was soon followed by dysentery, killing 50,000. During the first month of the epidemic, an emergency surveillance mechanism recorded crude mortality rates of 20 to 35 deaths per 10,000 population per day. Rapidly acquired surveillance

data guided relief efforts and targeted interventions to decrease the death rates to 5 to 8 per 10,000 per day by the second month of the crisis.⁶ The role of ongoing, pertinent health information in the settings of humanitarian crises that is iterative and available to those who must intervene is now a widely accepted component of disaster response and rehabilitation.

CURRENT PRACTICE

The first order is to establish objectives for the surveillance system. WHO outlines six objectives of surveillance applicable in emergencies: identify public health priorities, monitor the severity of the emergency by collecting and analyzing mortality and morbidity data, detect outbreaks and monitor the response to the outbreak, monitor trends in incidence and case-fatality from major diseases, monitor the impact of specific health interventions, and provide information to the Ministry of Health in the affected area.⁷ To achieve these objectives, the surveillance system should be simple and clear in its focus, easily understood by all who receive its information, and flexible to respond to new health problems and program activities.

The next step is to define the population of interest and its relationship to the health sector in the disaster area. What is the demographic makeup of the population (age, sex, ethnicity, etc.)? A discussion of establishing baseline population figures is found in Chapter 52. Where do people live both before and after the disaster? Where do people access health services, if at all? Where do health events occur? What is the structure and capability of the national health information system, and what government, nongovernment, and international agencies are working in the health sector?

To answer these questions, surveillance systems track *indicators*—qualitative or quantitative outcome measures that describe the state of the population in terms of health and the process and outcome of health services; they may correlate or predict the value or measure of a program, system, or organization. Their inherent value in a surveillance system is their ability to be tracked over time and compared with a baseline. Incidence, prevalence, mortality rates, and morbidity rates are the most common quantitative indicators during the emergency phase (Box 37-1).

BOX 37-1 DEFINITIONS OF QUANTITATIVE INDICATORS

- Incidence: The number of new cases of a disease that occur in a specified time period.
- Prevalence: The number of affected persons present in the population at a specified time divided by the population at that time.
- Morbidity rate: The number of persons who develop disease (incidence) or are affected (prevalence) during a specified time period divided by the number of people in the total population.
- Mortality rate: The number of deaths occurring in a population during a specified time divided by the number of people at risk for dying during that period.

A surveillance mechanism is built on the initial rapid assessments during the immediate disaster response. The outputs of those assessments should focus on the health problems that produce the highest morbidity and mortality, especially if the population affected is displaced. Mortality rates are the most important indicator for identifying a population under stress. Most commonly, the crude mortality rate (CMR) is used in emergencies to track the effects of disaster-generated infectious disease or injury. The practical initial quantitative baseline data captured at the onset of the disaster should include:

- Population size, specifically the total population affected; the population of vulnerable groups, including women, elderly, and children younger than 5 years old; and the influx and efflux of persons
- CMR (for calculation, see Chapter 52)
- Mortality rate for children younger than 5 years old (for calculation, see Chapter 52)
- Case-specific mortality and morbidity rates (for calculations, see Chapter 52)
- Nutritional status, specifically weight-for-height ratios of children ages 6 to 59 months

In the emergency phase, diseases most likely to cause death or significant morbidity, such as diarrheal illness (especially in a malnourished displaced population), acute respiratory infection, measles, and meningitis, should be the focus of surveillance. As the emergency evolves into the postdisaster setting, HIV/AIDS, tuberculosis, and sexually transmitted disease rates; chronic disease management; injury; immunization coverage (e.g., the Expanded Program on Immunization); and longer-term healthcare access should be included in ongoing surveillance efforts. Surveillance for the displaced disaster-affected population should eventually be integrated into the national health information system of the country, which is discussed later in this chapter.

Initial qualitative indicators will provide a basis for the needs of the population, especially the state of access to water, sanitation, and health services. Early qualitative critical indicators include:

- Immunization coverage
- Access to sanitation services and ample supplies of potable water
- Access to healthcare services
- Capacity or level of function of healthcare services
- Food distribution

As the disaster response becomes established and transitions into a postdisaster phase, qualitative indicators that examine the relief effort will guide resources and programming. Postemergency phase qualitative indicators may include:

- Ongoing access to healthcare services (the proportion of the population that can use the health service or health facility)
- Availability (the amount of services and resources compared with the total population)
- Health coverage (the proportion of the population that has received a given service)
- Quality of services (a measure of actual services)

- received compared with standards and guidelines)
- Equity in distribution of health resources (may explain why one subgroup of the population fares worse than another)
- Main program activities (for individual or groups of relief agencies involved in the delivery of care)

In terms of program performance, field epidemiologists recommend that indicators have SMART attributes, an acronym for “specific, measurable, accurate, realistic, and time-bound.”⁸ Indicators must be sensitive enough to monitor the impact of relief on the health problems and determine whether the effort is either having a tangible effect on the population or whether new strategies are needed.

Data Collection

The method by which data are collected is wholly dependent on the type of surveillance used. *Active* surveillance system data require a proactive seeking of cases through some type of sampling mechanism, usually direct reports from households or, more commonly, health facilities. Active surveillance is used more during the emergency phase. *Passive* surveillance systems rely on reports from the data sources, typically as cases present themselves. Passive systems lend themselves to long-term ongoing surveillance during the postemergency phase once health services are restored. Both have practical pros and cons. Active surveillance provides more accurate data but is far more labor intensive and thus more costly to implement. The need for accurate mortality rates and incidence of critical diseases justifies its cost and effort during the emergency phase. Passive systems by definition represent a self-selected population and may not accurately represent the greater population. Because passive systems are less costly and require less training, they are more practical for long-term surveillance. In either case, a surveillance system should have high sensitivity, that is, the ability to detect “true” cases of illness or injury.³

Often, one may hear the term *sentinel surveillance*. In such a system, selected data collection points (e.g., designated health facilities within the system) will be responsible for identifying and reporting specific diseases or health events. Specific segments of the population or specific locales in the disaster-affected population may be specially chosen for monitoring (e.g., the parameter weight for height in ages 6 to 59 months). Sentinel health events refer to a condition that has the potential to affect the health stability of the population—often a warning signal that the current level of preventive and curative care needs attention—and that should prompt immediate action. One case of meningitis presenting in a crowded displaced persons camp demands an immediate response from health agencies to avert an epidemic catastrophe.

Data collection tools, especially in the emergency phase, should be short, easy to use, readily understandable, and remain consistent over time. These tools should be designed to collect only the minimal, most essential information in a clear and unambiguous fash-

ion. The use of simple uniform case definitions for communicable diseases is critical. All health providers involved in surveillance should know, for instance, that a generalized rash of greater than 3 days’ duration *and* a temperature greater than 38° C *and* one or more symptoms of cough, rhinorrhea, or red eyes define a case of measles. Common diarrhea is classified as three or more liquid stools per day and duly recorded. In countries endemic for malaria, a temperature greater than 38.5° C in the absence of other infection is indeed malaria for data purposes. From these simple, yet sensitive, definitions, trends can be followed. Epi Info software, available free of charge from the CDC’s Web site, assists in generating data forms and in analyzing the data.

Data sources are most often health facilities, specifically health providers and hospital, emergency department, and clinic records. In displaced populations living in temporary camps, registration systems provide demographic data. Household surveillance may be necessary to identify basic needs. Other sources of demographic and health data include vaccination cards (often carried by mothers), burial records, networks of home visitors, and nongovernment agencies responsible for other sectors of the disaster response (e.g., water, sanitation, food, nutrition). Nontraditional sources of information may be useful, including police, fire, aid agencies, pharmacies, grave-diggers, and others. Abdullah and Burnham⁹ elucidate specific indicators with their relevant sources in Table 37-1. In settings in which the health services infrastructure may be destroyed by the disaster, government and nongovernment relief agencies—local and international—need to step in and establish a surveillance system in the course of providing preventive and curative care. The use of standardized patient data collection based on the CDC data classifications improves accuracy.¹⁰

Surveillance systems should be judged by their simplicity. Data collection should be an easy process and follow a logical format. Indicators should be representative of the population relevant to the disaster and the disaster phase (e.g., diarrhea is more likely to be a problem than hookworm infestation in an emergency). Data outputs should be timely to identify outbreaks and should be reliable (using standard case definitions, for example). Data collection must occur in an ongoing fashion at regular intervals but be flexible to adapt to new health problems or sudden program changes.

Analysis, Interpretation, and Dissemination

During the emergency, data should be collected daily and reported weekly to all government and nongovernment relief agencies working in the health sector. Postemergency phase data may likely be recorded daily but collated monthly for analysis. During all phases, surveillance data should be sent in either paper or digital form to a central location at the field level for analysis. Most countries have some type of ongoing surveillance mechanism to track the burden of disease. Usually, this is a component of a broader health information system housed within a Ministry of Health and has some means

TABLE 37-1 SURVEILLANCE INDICATORS AND SOURCES OF INFORMATION

Rights were not granted to include this table in electronic media.
Please refer to the printed publication.

From Abdallah S, Burnham G, eds. *The Johns Hopkins and Red Cross/Red Crescent Public Health Guide for Emergencies*. Baltimore: Johns Hopkins University; 2000.

for data analysis (in the United States, state and local public health offices and the CDC). A country's health information system, assuming it remains intact after the disaster, should provide baseline predisaster health information on communicable and noncommunicable diseases. From this, one may see background health information, such as seasonal variability in endemic diseases, the burden of chronic disease, patterns of injury, and other periodic health trends, from which to evaluate newer surveillance data.

The analysis of surveillance data should focus on the clustering of events over time or the clustering of events within specific subgroups of the population.¹¹ To that end, the analysis should emphasize trends in time, place, and person. The interpretation should highlight the needs and priorities and, where possible, be referenced against "normal" values or indicator thresholds. What matters most is how indicators change over time and how these changes may be linked to programming.¹² The use of graphs and maps using geographic information system (GIS) software makes interpretation more meaningful to stakeholders. The flow of surveillance data must be coupled with an action-oriented information system whose primary task is to get information to those who need to know and can act.

PITFALLS

A surveillance system must have high sensitivity—that is, the ability to detect true cases of a given health problem

of interest within the population. The greatest enemy of an effective surveillance system is underreporting by those tasked to collect the data for a variety of reasons.

First, surveillance depends on a flow of information; during a disaster, established systems of information flow are easily disrupted (e.g., a health center is destroyed, the population migrates, communications and transportation networks are damaged). Also—and this is true especially of passive type systems—if health providers lack interest, do not see the value in the iterative data collection process, or feel overworked and have limitations on their time due to patient care to report data, the incentive to find and report cases will diminish. Lack of interest is often due to health providers not being provided the analyzed information in the dissemination process and thus not able to appreciate its beneficial effect on the health of the population. Underreporting as a consequence of any these reasons undermines the strength of a surveillance system.

Another concern is the source of information. Relying on health-facility-based surveillance information if the population does not have adequate access to formal healthcare raises the question of whether a health-facility-based surveillance system accurately represents the health needs of the population.¹³ This typically means that emergent and urgent health issues are not reliably captured and appreciated by those who could make a difference.

Finally, meaningful analysis and interpretation capacity does not exist in many countries. Despite readily accessible tools, such as Epi Info, and the presence of

computer-savvy technical staff who can manage data, there is often a need for personnel with public health understanding and backgrounds to interact with the data to explain its significance to disaster managers and other key stakeholders, who may have only a nominal understanding of the ramifications of public health data for a population.

Management of Mass Fatalities

Nelson Tang and Chayan Dey

Modern complex disasters have the ever-increasing potential for creating large numbers of deceased, the management of which is of specific importance to the planning and operational response to such events. Historically, disaster consequence management with regard to large numbers of deceased human beings has been a relatively poorly contemplated aspect of response and recovery. Current concepts of operations in disaster medicine place increased emphasis on the management of mass fatalities.

A *mass fatality incident* is generally defined as one in which the numbers of deceased overwhelm the capabilities of local jurisdictions, including the coroner and medical examiner, to appropriately deal with them. Consistent with broader disaster response mechanisms, the management of fatalities resultant from a disaster, whether natural or manmade, requires the effective coordination and deployment of multiple tiers of resources and trained personnel. The timeliness of response to large numbers of fatalities becomes further significant when considered in the context of the families of victims and their need for the identification, documentation, and disposition of the remains of their kin.¹

In the United States, there are specific federal resources that may be made available to local jurisdictions for the response to mass fatalities in certain circumstances through the Department of Homeland Security (DHS) and the Federal Emergency Management Agency (FEMA). Today, increased awareness exists with regard to the effects of managing large numbers of deceased on rescue and healthcare workers.

HISTORICAL PERSPECTIVE

Conventional paradigms in disaster medicine dictate that the deceased or unsalvageable victims of catastrophic events are to be triaged as expeditiously as possible to a morgue, away from patient care and medical response activities. It is reasonable to expect, however, that local morgue facilities will be quickly overwhelmed by the sheer number of deceased in the aftermath of a large-scale disaster. The increased likelihood of terrorist-instigated disaster scenarios and the potential use of weapons of mass destruction further complicate the

management of the deceased. Concerns for decontamination before disposal and, additionally, the criminal investigation and evidence collection requirements of the law enforcement response to such events make the prospect of removing large numbers of deceased individuals a highly complex undertaking.

In contrast to the earliest notions of mass burials or cremations, more recent event-based disaster experiences have demonstrated that fatalities numbering in the hundreds can be effectively managed, including the organized transportation, processing, identification, and disposition of all bodies recovered. Much of this experience has been derived from civilian and military aviation disasters.^{2,3}

Two fundamental assets of forensic medicine—radiographic and dental investigation—have proven to remain essential in mass fatality management. Radiographic screening for foreign bodies, personal effects, dental and surgical artifacts, and occult skeletal injury are well-established techniques in modern forensics. In addition, positive radiographic identification of casualty victims by comparison with available individual antemortem records is similarly effective.^{4,5} The evaluation of dental evidence and comparative data for disaster fatality identification are essential tools, and the role of forensic dentists and dental professionals has been described in mass fatality events.^{6,7} Such conventional forensic approaches have direct application to mass fatality events, although the technical and operational aspects of such efforts would appear to remain logistical challenges.

CURRENT PRACTICE

In the United States, under the National Response Plan, the National Disaster Medical System (NDMS) is tasked to provide victim identification and mortuary services in declared disasters (Box 38-1).⁸ To accomplish this mission, the concept of the Disaster Mortuary Operational Response Team (DMORT) was developed in the early 1990s. Directed by the NDMS under FEMA, DMORTs are composed of medical and forensic volunteers who are activated in the event of a disaster and have specific training and skills in victim identification, mortuary

services, and forensic pathology and anthropology methods (Box 38-2).⁹ Often, disaster medical assistance team components are co-deployed with DMORT personnel to provide maintenance and emergency healthcare to personnel involved in mass fatality operations. These operations may involve a large number of personnel working in austere conditions for a prolonged period, necessitating medical care maintenance.

DMORT members are required to maintain appropriate and current certifications and licensure within their respective disciplines. During an actual emergency response, DMORTs work under the guidance of local authorities by providing technical assistance and personnel to recover, identify, and process deceased victims.¹⁰ At least one of these teams has expertise in handling contaminated or infected remains.

- Coroners
- Pathologists
- Forensic anthropologists
- Medical records technicians
- Fingerprint technicians
- Forensic odontologists
- Dental assistants
- Radiologists
- Mental health specialists
- Funeral directors
- Computer professionals
- Administrative support staff
- Security and investigative personnel

From Federal Emergency Management Agency. Resource: Disaster Mortuary Operational Response Team (DMORT). Available at: http://www.fema.gov/preparedness/resources/health_med/dmort.htm.

The Response Division of FEMA currently maintains two Disaster Portable Morgue Units (DPMUs) that may be deployed to support an NDMS DMORT response (Fig. 38-1). The DPMU is a depository of equipment and supplies for deployment to a disaster site. It contains a complete morgue with designated workstations for each processing element and prepackaged equipment and supplies. Both DPMUs are staged at FEMA Logistics Centers, one in Rockville, Md., and the other in San Jose, Calif.¹⁰

The U.S. military maintains rapidly deployable multidisciplinary resources capable of the rapid recovery, examination, identification, and return of physical remains in response to mass fatality disasters. In 1997, the U.S. Army Europe developed the Disaster Mortuary Affairs Response Team (DMART), patterned after the civilian DMORT concept. This is the only team in the military that combines Mortuary Affairs with forensic personnel to support the combatant commander.¹¹

Disaster victim identification (DVI) is a term that has been applied to procedures used to positively identify deceased victims of a multiple casualty incident. Positive identification is required for both legal considerations and for the peace of mind of the families of victims. In general, DVI should not begin until all of the survivors have been identified and transported from the scene. The goal of DVI is to identify all victims by matching antemortem and postmortem data.

The International Criminal Police Organization (Interpol) has developed a system of standard procedures for DVI. Written procedures of the Interpol system exist within the *Disaster Victim Identification Guide*.¹² Although guidelines for DVI must be adapted to individual circumstances, this general approach may be implemented in a variety of disaster settings. Regardless of the actual methods used, it is imperative that DVI be conducted in a timely, accurate, and thorough manner and in keeping with international standards.

The increasing complexity and scale of modern disasters, further amplified by terrorist-orchestrated disasters, have driven the technological advancement of forensic investigation of mass fatality incidents. The development of forensic bioinformatics and high throughput DNA analysis techniques as means for victim identification have been reported as a specific outcomes driven by the immediacies of the Sept. 11, 2001, terrorist attack on the World Trade Center in New York City.^{13,14} The future of disaster consequence management is likely to demonstrate the further proliferation of such technically advanced procedures for ultra-rapid, mass-scale disaster victim identification.

PITFALLS

Recent historical experience with regard to major disasters has demonstrated that effective response to mass fatalities is a distinct possibility. Nevertheless, it would be erroneous to conceptualize such responses without the skills and intervention of dedicated professionals with pre-existing expertise in forensic medicine, pathology, mortuary services, and deceased identification and processing.

FIGURE 38-1. A-E, EgyptAir crash mass fatality recovery operations. B and C show the DPMU in its setup stage.

Reliance on local resources is unlikely to be sufficient. Coordination of efforts by local authorities with federal specialty teams is essential for the timely and successful completion of mass fatality operations. Disaster planning and response must include appropriate thresholds for

activating available mechanisms and deployment of specific dedicated resources for mass fatality management.

Effective postmortem identification of disaster victims has both pragmatic and psychosocial significance and may no longer be considered a luxury but rather a

necessity. For legal, ethical, religious, and financial purposes, successful identification of the deceased has considerable significance. The timely issuance of death certificates may have direct import for the registration of the dead and for use in insurance and other possible death benefits claims and is likely to be a requirement for final disposition of individual remains.¹⁵ Definitive victim identification and the expeditious release of physical remains allow bereaved families of victims to make funeral and burial arrangements consistent with religious and individual beliefs. In addition, in the event of multinational disaster scenarios, transport considerations may create additional urgency and pressure for the early release of remains.

The infectious risk of handling corpses is not well understood or quantified. Conventional wisdom dictates that disaster victim recovery, whether living or deceased, be performed with universal adherence to communicable disease protection. Infectious pathogen precautions should be maintained throughout fatality recovery, processing, forensic examination, and disposal. If the disaster event holds the possibility for a chemical or biological weapons attack, workers must have access to personal protective equipment commensurate with the threat. Most disaster sites will present multiple physical and environmental dangers, including debris, hazardous materials, and structural instability. Fatality management workers must be briefed appropriately of such hazards and not be placed in unnecessary risk of physical injury.

The actual scope and extent of the impact of confronting and managing mass fatalities on healthcare and rescue workers are not completely known. There is evidence to suggest that medical training and clinical experience may not provide the needed degree of emotional and psychological protection, as has been previously believed. Instead, it is plausible to expect that significant variability with regard to emotional reactions and psychological vulnerabilities exists among disaster responders before, during, and after exposure to mass fatality events.¹⁶ Prior study in this area suggests that the adverse psychological effects, although not permanent, of disaster victim body handling and identification work are not necessarily correlated with lack of experience or training.¹⁷ It is increasingly common for modern disaster response plans to provide for debriefing and poststress exposure psychological support for responders. It is prudent to consider additional focused support services for those directly tasked with handling and identifying physical remains of disaster fatalities.

CONCLUSIONS

Disasters that engender mass fatality conditions are likely to overwhelm local and even regional resources and the capacity to effectively deal with such contingencies. Analysis of consequence management demonstrates that

an integrated, coordinated approach to response can effectively manage large numbers of fatalities. Specific federal assistance is available to augment local resources in the response to mass fatality situations. Through the NDMS, DMORT specialist personnel and DPMU facilities may be deployed under certain circumstances.

Although generally contemplated as a second-tier response consideration, after the management of living victims, the appropriate handling, identification, and disposition of the deceased nevertheless have specific importance. Vigilance must be maintained for the physical safety of personnel managing disaster fatalities, and provisions must be made for appropriate personal protective equipment. The handling of human remains, particularly in a mass fatality disaster, may have a variable but significant emotional and psychological impact on personnel responding to these events.

Disaster Management of Animals

James M. Burke

The current geopolitical climate has forced the United States to explore contingency plans for future environmental disasters. Although most of the research along these lines is focused on human safety, the animal and agricultural aspects of disaster management also need to be explored. Since natural disasters are a more frequent risk to animal populations than possible biological or terrorist threats, the protection of these resources demands proper consideration.

U.S. Agriculture, a \$100 billion business, is an important nutritional source and helps sustain our economic growth and military readiness.¹ Concentrating animals into larger facilities to provide abundant food sources increases the agricultural impact of a biological disaster or terrorist threat. The large numbers of companion animals in urban areas, meanwhile, should also be considered during an evacuation, since most disaster shelter facilities do not accept animals. Overall, a large number of animals—both livestock and pets—are likely to need care during a disaster.

Analysis of past disasters highlights some mistakes, but lessons may be learned from them. Large-scale natural disasters, such as hurricanes Andrew and Floyd in 1999, may be viewed as test scenarios from which future contingencies can be developed. Evaluating the mobilization, transportation, and housing of displaced companion animals and livestock helps prepare pet owners and animal producers for future events. Not all contingency factors can be addressed in every disaster plan, and for this reason, a flexible, well-thought-out plan is necessary.

According to the National Academies Board on Agriculture and Natural Resources' report, "Countering Agricultural Bioterrorism," not only is America vulnerable to terrorist attacks against agriculture, but insufficient plans are in place to defend against such attacks.² The crippling effects of the foot-and-mouth disease epidemic of 2001 illustrate the local economic disruption and global impact such events entail.³ Although biological attacks will not cause widespread famine, they could have a direct effect on the national economy, public health, and the public's confidence in the food system. Plans need to be drafted now to provide a framework in which a safe, continuous supply of food can be guaranteed, epidemic disease outbreaks can be prevented, and proper care for injured animals can be ensured.

HISTORICAL PERSPECTIVE

As some of history's most recent disasters show, animal healthcare, veterinary infection control, control of stray animals, and the revival of veterinary infrastructures are the primary areas that need to be addressed in effective implemental models developed for the future.

On Aug. 24, 1992, hurricane Andrew ripped through southern Florida, leaving thousands of animals injured, abandoned, or dead. Relief efforts became hampered as organizations and volunteer groups lacked a central command structure. These groups, though well intentioned, were unable to coordinate the necessary supplies and medical resources in a cohesive effort to help those areas most devastated by the hurricane.

On Sept. 16, 1999, hurricane Floyd devastated North Carolina, affecting poultry, pork, and cattle production, as well as horses, cats, dogs, and other pets. North Carolina residents, due to unsubstantiated, predicted dangers in previous media-hyped disasters, ignored calls for evacuation. The lack of pet-friendly evacuation shelters, in addition to the lack of public preparedness, contributed to evacuation failures. Such failures endanger not only animals but their human owners as well. North Carolina State University's College of Veterinary Medicine was able to re-establish a veterinary infrastructure, contributing to the success of the disaster management operation. With its large number of trained personnel, resources, and medical supplies, the college was able to immediately take charge of animal care and control issues, organizing volunteers. In addition to a large number of volunteers, enormous amounts of food and medical supplies were donated, and transportation was made available to help agencies contend with the disaster.

During the hurricane Floyd disaster, medical care for animals was administered through a three-tier system. Tier 1 consisted primarily of vaccinations for cats. Tier 2 included the testing of animals for heartworm infection, and other diagnostic tests. Tier 3 treatments included surgical and medical stabilization of injuries.³

On April 25, 1994, a tornado struck West Lafayette, Ind., destroying 67 homes and 60 mobile homes. The civic response to this incident is an example of a lack of evacuation procedures that resulted in massive pet abandonment by individuals in an urban location. Pet

abandonment is a consequence of unplanned or poorly executed evacuations. Human-animal bonds are strong, and during a disaster, such bonds may influence one's decision to re-enter a disaster area to retrieve a family pet. Such decisions may pose significant risks not only to individuals and families, but also to emergency personnel, who may need to become involved in rescue efforts.⁴ Statistically, owners who regularly visit their veterinarians are less likely than those who do not to lose their pets during evacuations. Individuals with weak or poor human-animal bonds, who have low levels of disaster preparedness, or who own many animals are more prone to leave their animals behind during a disaster.⁵ Although pet abandonment is common during disasters, in a national survey the proportion of animals abandoned during disasters was similar to the proportion of animals relinquished to 12 U.S. animal shelters.⁵ Pet evacuation failures generally result from low levels of pet care. Promoting responsible pet ownership that includes planning for emergencies, both natural and manmade, is a logical strategy to make owners more responsible for the evacuation of their pets.

On March 4, 1996, a train derailed near Weyauwega, Wisc., causing a fire to erupt in the train's propane-filled cars. Local residents were asked to evacuate due to fears of a major explosion. Risk factors influencing the failure of owners to evacuate the area's cats and dogs included a weak human-animal bond, logistical challenges, and generally low levels of disaster preparedness. During the Weyauwega disaster, 15% of all pet owners were at work and unable to evacuate their pets. The most common reasons for failing to evacuate pets included owners thinking that they would not be gone long and that the evacuated areas were safe for pets.⁶ Outdoor cats were at higher risk of evacuation failure since they are more difficult to catch and transport. The higher incidence of the failure to evacuate cats compared with the failure to evacuate dogs likely reflects the greater ease with which dogs can be caught, restrained, and transported. It could also reflect the assumption that cats can "fend for themselves" if left outdoors. Interestingly, households with a high number of cats are more likely to leave a dog behind during evacuation procedures.⁶

In November 1990, western Washington experienced severe flooding. Dairy farmers who were surveyed were asked to evaluate the amount of equipment and personnel available to evacuate cattle, numbers of cattle evacuated, time required for evacuations, and the destination and care of the animals. Financial loss from cattle deaths, illnesses, and halts in production was estimated at \$2,786,629.⁷ Help for evacuation was readily available from family members, employees, and friends. Because of adequate notice, 5000 animals were evacuated in 20 hours. Evacuated cattle were housed at neighbors' farms, at friends' homes, on high ground, and at a vacant dairy. Not one cow went more than 2 days without fresh water or normal rations. Unfortunately, however, most of the farmers did not plan in advance on where to evacuate and how to care for their animals. In hindsight, farmers said they could have sheltered all of their animals if necessary. Overall, however, it was adequate time that led to the successful evacuation of a large number of animals to

safe locations. On shorter notice, such a successful evacuation may not have been achievable.

Horse owners typically treat their animals differently than owners treat general livestock, and they usually have been able to move most, if not all, of their horses within 90 minutes. Data suggest that the relatively small number of horses kept on a farm and the high emotional bond between owners and horses increase their chance of being evacuated in a timely manner. A large number of cattle, by contrast, is not suitable for quick evacuation, and horses are easier to find and transport. According to horse owners in Madison County, Ky., 100% of the horse population could be evacuated if a 12-hour evacuation notice were given.⁸

CURRENT PRACTICE

The first priority in disaster relief is protecting and saving human lives. Animals have traditionally been viewed by emergency management officials as property, and therefore, they receive much less attention than humans. Animal owners, on the other hand, consider animals either as an important source of income or as part of the family. Animal management during natural disasters is best accomplished with a plan created by state and local officials that provides a detailed framework in which to implement care during evacuations. Such a plan's objective should be to bring some type of logistical structure to the chaos that occurs during and after a disaster. As part of this plan, it is essential that veterinarians understand disaster preparedness so that they can integrate themselves more effectively into national, state, and local disaster management systems.

The first step in an adequate disaster plan is denoting a clear chain of command that includes the delegation of responsibility. Without such a framework, independent groups may unintentionally direct resources away from needed areas. State veterinary agencies and practitioners will need to take responsibility for assuming leadership roles to organize animal professionals and lay volunteers. These roles may include developing liaisons with representatives from the Department of Homeland Security (DHS), Department of Health and Human Services, the American Red Cross, National Urban Search and Rescue Response System, and the U.S. Army Veterinary Core at the Department of Defense. The U.S. Army Veterinary Core is activated at the request of a state's governor via the president of the United States. DHS provides Veterinary Medical Assistant Teams (VMATs) to assist local authorities during a federal emergency. VMATs provide care to injured animals and assist with preventative measures to maintain human health and safety. The U.S. Department of Agriculture is responsible for assessing food supply safety issues during disaster situations.⁹

Once a command structure is in place, pet owners need to identify the types of disasters for which they are at risk. To assist pet owners in this process, it is recommended that veterinarians promote the creation of individual household disaster plans. Farms and large agricultural centers with a large number of animals will need to provide an equally detailed evacuation plan that

ensures the appropriate feeding, sheltering, and burial of livestock.

VMATs should be called into emergency situations to augment state and local veterinary resources until a self-sufficient response solution is reached in the disaster area. VMATs should be available immediately after a disaster, slowly tapering off as local needs decrease and local resources expand to meet the needs of the victim population. VMATs consist of two veterinarians, four veterinary technicians, and one to three logistical support personnel.⁹ The director of the Offices of Emergency Response within DHS and the American Veterinary Medical Association should activate VMAT intervention in an emergency. With necessary medical equipment and supplies at their disposal, these teams will operate as mobile units in disaster areas, responding to advice from regional veterinary activities commanders.¹⁰

Identifying potential problems in a disaster begins with the process of eliminating any mitigating hazards that may be present on a farm or in an animal-impacted area. Alternative housing and shelter locations, clean food and water access, and accessible transportation must be designated before successful egress can occur. Repairs to barns and buildings will help to decrease the number of potential dangers during evacuation procedures. Most farms have the manpower and resources to move a large number of animals.⁷ Farm cats and dogs should be placed in a disaster-proof location, or, because they generally stay close to their homes, turned loose. If shelter cannot be found for aggressive animals, euthanasia is the most humane method of treatment.

Animals that are important to agricultural production or have sentimental value need to be identified ahead of time so they can be transported rapidly. Large animal transports may present a problem to human evacuation, clogging already busy exit routes; therefore, alternative evacuation routes need to be considered in advance. In the event that animal evacuation is not possible, sources of shelter, food, and water will need to be designated, and a plan that addresses how best to re-enter the disaster area to attend to the animals needs to be in place.

It is important that local kennels and pet shelters are able to accommodate the influx of small animals during a disaster. Veterinarians are the best channels for communicating with local pet owners about the safe evacuation of their pets. The American Red Cross, although it does not shelter animals, should also be able to provide information, in coordination with local animal shelters, on how to care for pets in evacuation areas.

Veterinarians play an important role during disasters. Their primary responsibilities include control of disease factors and disease transmission, herd management, animal healthcare, search and rescue operations, animal control, and disaster assessment. Even though it is important that veterinarians have the resources available to locate and call on appropriate experts during a disaster, they also will need to address the proper sheltering of animals, provide advice to animal owners on nutritional requirements, care for sick and injured animals, tend to the proper disposal of carcasses, provide housing to animals, and manage food safety. Veterinarians should have detailed maps of animal centers in their areas, such as

veterinary hospitals, boarding kennels, fairgrounds, race-tracks, and other evacuation locations, including slaughterhouse facilities. Veterinarians should also organize therapeutic intervention methods, systems, procedures, and processes to prevent potential illnesses.

Industrial livestock production facilities, as well as home farms, may see a large number of animal habitats destroyed during a disaster, jeopardizing vital food stores. Diseases, exacerbated by impaired food and water supplies, could lead to outbreaks of food poisoning, typhoid, cholera, infectious hepatitis, and gastroenteritis. Removal of fences and enclosures results in the release of animals that subsequently roam unrestricted, increasing their interaction with wildlife, domestic animals, and human populations, providing vectors for potential disease transmission.¹¹ Veterinarians with training in food and meat hygiene should decide which foods (e.g., milk or meat products) are potentially unsafe and which foods are acceptable for human consumption in the given disaster circumstances.

The American Veterinary Medical Association has created a disaster preparedness series, which is included on its Web site, designed to educate both pet owners and the large industrial animal producers on the natural and technological aspects of disaster preparation.¹² The University of California-Davis Veterinary School also provides online information for facilities planning to offer animal care during evacuations. Animal care operations can find additional printable forms online to help organize the influx of evacuated animals.

Disasters may occur when owners are away from home. In such instances, stickers placed around the homeowner's property in advance can aid rescue personnel. These stickers should contain information pertaining to the types of animals located on the property, the location of the animals, their possible hiding spots, and the location of evacuation supplies. Owners should designate a neighbor familiar with their animals and evacuation plans to be responsible for the animals in the event that they are not at home when a disaster occurs. Identification tags, including rabies and license tags, will help reunite owners with their pets after a disaster. Identification should include the owner's name, home address, phone number, and an out-of-state phone number of someone who can be contacted in the event of an emergency. Suggested methods for identifying large and small animals are included in Box 39-1.

During an evacuation, it is best to separate animals into individual evacuation areas—based on household location and species—to decrease disease transmission.

Large animal evacuations are more difficult to manage than small animal evacuations. Specifically, animals unfamiliar with trailers provide a unique handling and capture challenge. A key recommendation for evacuating larger animals is to acclimate the animals to transportation equipment and the evacuation process in advance.

The evacuation of exotic animals, such as birds, amphibians, and reptiles, can be equally challenging. Birds are best transported in small, securely covered containers to prevent injury. Cages should be covered and placed in quiet locations to decrease the stress of evacuation. Amphibians can be transported in watertight plastic bags

BOX 39-1 METHODS OF LARGE AND SMALL ANIMAL IDENTIFICATION

and plastic containers, one species per container. Small pet reptiles can be transported effectively in pillowcases, sacks, or transfer carriers. Using the same water that an amphibian inhabited before the evacuation will help minimize physiological stress. All exotic animals should be provided with clean food and water every day, including dietary supplements unique to that animal. Once animals arrive at evacuation facilities, special care must be taken to monitor water and air temperature, humidity, and lighting.

After intake areas at evacuation sites are established (Box 39-2), animals need to be secured in cages or on leashes and properly identified. Identification includes taking a picture of the animal with the owner, if the owner is available. Intake information should include a unique number for the animal and its date of birth, sex, and breed. Bite alert badges, if relevant, should be placed on cages or on the animals' collars. Unless the animal is injured and needs to see a veterinarian, shelter personnel should then take the animals to their perspective housing areas. Injured animals should be taken to a triage area. Intake for dead animals (including strays) should be handled in much the same manner, except that carcasses should be placed in properly designated areas or disposable containers.

The treatment of injuries and infectious diseases needs to occur before an animal is transferred to an intake area and placed among other evacuated animals. Triage sites are to be used as temporary holding facilities where veterinarians can determine whether an animal is stable enough to be transferred to a housing facility. Animals determined to be in life-threatening situations with reasonable prognosis of a full recovery should be triaged to one area, animals with nonlife-threatening injuries

BOX 39-2 POTENTIAL EVACUATION SITES

Veterinary hospitals
Fairgrounds
Racetracks

Animal shelters

should be triaged to a second area, and uninjured animals should be transferred to a third area.

Information on housed animals should include the following:

1. What food and what quantity of food the animal should be fed (Table 39-1)
2. Whether, and how much, the animal is eating
3. Whether the animal is drinking its water
4. Whether the animal is defecating in the cage, and whether stools appear normal
5. Whether the animal appears mentally or physically well

Sheltered animals need to be walked for a total of 3 hours per day, no longer than 15 minutes per walk. Information regarding larger animals needs to be noted, such as their movements or lactations. Abnormalities or unusual behavior occurring in either large or small animals, when properly recorded, will alert veterinary and housing personnel of a potentially sick animal.

Once a disaster is declared over, all animal habitats used before the disaster need to be cleaned and cleared of potential hazards before animals are released back into those environments. Areas surrounding buildings and facilities need to be cleared of any sharp objects, dangerous materials, and wildlife. Large animals should be released into safe, enclosed outdoor areas. Because small animals may encounter dangerous wildlife and other debris if allowed outside unsupervised and unrestrained, they should be released indoors. Animals that may have been left behind without food sources should be reintroduced to food in small servings, gradually working up to full portions. Uninterrupted rest and sleep will help the animals to recover from trauma or stress.¹²

PITFALLS

Traditionally, veterinary public and animal health concerns in disaster management have focused primarily on food safety and supply, injury, and treating infectious diseases. Data, however, suggest that it is equally important to focus on the animals left behind by their owners. In preparation for future events, the evacuation of pets along with human household members must be prioritized.

In surveys of previous disasters, most pet owners proved self-reliant, requiring no public services. Such self-reliance should be encouraged. Unfortunately, however, owners who evacuate pets can hinder the efforts of

TABLE 39-1 HOUSED ANIMALS' FOOD AND WATER REQUIREMENTS

ANIMAL	WATER PER DAY	FEED PER DAY
Cat/dog	1-3 quart per animal	Varies
Cows/horses	7-9 gallons	8-20 lb hay
Poultry	0.5-1.5 gallons per 10 birds	2-4 lb per 10 birds
Sheep/swine	1-4 gallons	3-8 lb hay or grain

emergency management officers, who are primarily focused on evacuating people. In New York City, after a scaffolding collapse, emergency management personnel initially told people to leave their animals, and several days passed before pet owners were allowed to tend to their animals. Later, emergency management officials were prosecuted for preventing pet rescue.⁵ Better coordination with local animal health officials may prevent such problems.

Thirty percent of respondents in one city suggested that they would not evacuate with their pets in an emergency because they would not be able to catch or transport them.¹² Pet evacuation failures occur independently of geographic location and weather conditions at the time of the disaster. Sociodemographic risk factors of pet abandonment, however, are usually present before disasters strike. They include low pet attachment, dogs living outdoors, and owners not having carriers for cats. Therefore, to promote solid animal evacuation practices, animal owners require education by local animal health personnel. In addition, emergency medical systems somewhat promote negligence by pet owners by forcing them to keep their pets at home during an emergency. Further, local emergency shelters do not provide suitable housing for people and their animals. In some instances, individuals abandon evacuation shelters because they are afraid their pets will be jeopardized. Most shelters do not provide any means of animal support because they do not want, or cannot afford, the liability involved in housing both humans and pets. One solution would be to create pet-friendly shelters where humans can evacuate with their animals. Unfortunately, at present, the American Red Cross only has rooms and resources to manage the large number of displaced people and not their pets.⁴

Farms, which usually have large numbers of animals of different species, present unique evacuation planning problems. Most farmers are middle-aged, well-educated individuals living in rural areas. These individuals tend to be somewhat skeptical about evacuation orders delivered through radio and television and instead rely heavily on themselves and their neighbors for information. In one survey, farmers prioritized their evacuation plans by placing family safety first, farm and home security second, and animal concerns third.¹³ If cattle needed to remain on the farm, most farmers suggested that 3 days of feed and water would be available. A majority of the farmers surveyed agreed that within 2 weeks, additional

feed and water would be needed.¹³ Further complicating matters, few areas in disaster situations [SW1] are big enough to accommodate a large number of animals from multiple farms. Therefore, preplanned evacuation areas to corral valuable herd animals need to be identified in advance. Farms can use numerous individuals, family members, employees, and friends to help transport herds of livestock, provided that adequate notice is given. The sheer amount of work necessary to transport agricultural animals necessitates a larger timeframe, allowing greater compliance and removal of animals to safety.⁷ The difficulty of gathering a large number of animals, both agricultural and domestic, suggests that animal control personnel need to be more centrally included in evacuation planning and assistance teams.

Urban Search and Rescue

Gregory Ciottone

Urban search and rescue operations are an integral part of the response to disaster. Advances in the recovery of victims trapped for days in the aftermath of a catastrophic event have been some of the most significant improvements in disaster response over the past 25 years. Unlike the disasters of old, recovery of victims now may occur days after the event, resulting in significant changes in the duration of the search and rescue phase of the response. In addition, the emergence of confined space medicine (CSM), the medical care of victims trapped in very small areas, has brought a level of sophistication to the search and rescue operation not previously seen. The study of CSM defines the unusual entrapment situations and unique medical scenarios encountered when caring for victims in collapsed structures.¹ Although there are varying circumstances under which search and rescue may be deployed, in most cases the Urban Search and Rescue (US&R) Task Force (TF) model has been used to safely recover victims of disaster trapped under rubble. The nature of the disaster dictates the techniques and equipment that US&R TFs bring to bear, along with the expertise and experience required to locate and recover trapped victims.

Even though a discussion of the specific techniques used by US&R TFs is beyond the scope of this book, it is essential for any disaster responder to have an understanding of the role of US&R in the overall response. It is very likely that during disaster medicine operations, significant overlap will occur with US&R TF operations. It may be that disaster medicine specialists are called on to provide medical support for specific US&R missions or that these specialists are faced with providing patient care to the victims rescued by US&R personnel. In either case, understanding the basic principles of urban search and rescue, such as the extrication of victims with crush syndrome, is necessary.

HISTORICAL PERSPECTIVE

Search and rescue operations have been a part of disaster response from the earliest recorded events. A report of the attempted rescue and recovery of victims from under the soot caused by the Mount Vesuvius eruption of 79 AD by Pliny the Younger stands as one of the earliest descrip-

tions of search and rescue in a disaster. In virtually all disasters, either natural or manmade, there has been some attempt to rescue victims lost and presumed trapped. The desire to rescue others stricken by disaster crosses cultural bounds and is ingrained in all of us. Until recently, that recovery process typically involved actions by lay people in close proximity to the disaster scene. Formal search and rescue concepts did not develop in the United States until the 1980s. Before that time, any search and rescue activities were typically unorganized and lacked formal training and guidelines. In 1988, after the Office of Foreign Disaster Assistance (OFDA) established teams that responded to several international earthquakes, the Robert T. Stafford Disaster Relief and Emergency Assistance Act of 1988 and the Federal Response Plan (FRP) outlined a specific need for search and rescue as part of the response to disasters.² The Federal Emergency Management Agency (FEMA) then created the National Urban Search and Rescue Response System for the rapid deployment of specialized teams on a national level.^{1,3} Homeland Security Presidential Directive 5 later mandated the creation of a new National Response Plan. As a result the Department of Homeland Security (DHS) created the National Response Plan of 2004, in which 15 areas are named as Emergency Support Functions (ESFs) required for disaster response, with urban search and rescue being one of them (Box 40-1). This organizational configuration remains today, with USAR teams ultimately falling under FEMA and DHS.

CURRENT PRACTICE

USAR TF Composition

Currently there are 28 US&R TFs in the United States, all under the direction of the DHS.⁴ Each TF is designed to be rapidly deployed to disaster sites anywhere in the country, with a goal notification to departure time of 6 hours. Each is equipped and trained to be completely self-sufficient for 72 hours in a disaster zone, and each includes four categories of personnel: search, rescue, medical, and technical. There are 38 specialized positions on the TF, each filled with at least two people. TF Medical Team personnel are physicians and paramedics.

BOX 40-1 EMERGENCY SUPPORT FUNCTIONS

ESF 1	Transportation
ESF 2	Communications
ESF 3	Public works and engineering
ESF 4	Firefighting
ESF 5	Emergency management
ESF 6	Mass care, housing and human services
ESF 7	Resource support
ESF 8	Public health and medical services
ESF 9	Urban search and rescue
ESF 10	Oil and hazardous materials response
ESF 11	Agriculture and natural resources
ESF 12	Energy
ESF 13	Public safety and security
ESF 14	Long-term community recovery and mitigation
ESF 15	External affairs

Within each category, positions are filled with personnel possessing specific specialty training. These include specialists in lifting structures, bracing structures, use of dogs, and use of listening devices and hazardous materials specialists and communications specialists, to name a few.³ The search team members' responsibility is the location of trapped victims, whereas the rescue team's responsibility is to remove them. Rescue team members also assist with the shoring up of the structure. The technical team manages the liaison with local resources, evaluates and shores up the structure, provides hazardous material identification and management, and manages communications. They are the logistical arm of the TF. The medical teams provide emergency medical care to victims and injured TF members throughout the duration of the operation. They may also be counted on to provide prolonged medical care to victims trapped in the rubble and initial emergency search canine care. The advent of CSM has resulted in an increase in the sophistication of medical care provided by the US&R medical teams.

US&R personnel use personal protection equipment (PPE) specific to the work they must do. The use of respiratory protection in the form of either a mask or self-contained respirator is almost always necessary. There are often hazardous material problems within a work site that may cause the release of noxious gases. At a minimum, dust is always a factor when working under the rubble. Lighted helmets are also required to protect against falling debris, along with some form of eye protection, such as safety goggles. Protective coveralls made of a strong material, such as polyethylene (Tyvek), are used, along with elbow and knee padding. Latex gloves should always be used under leather ones as barrier protection against hazardous materials or bodily fluids. Search and rescue personnel also carry an assortment of equipment necessary, including a safety rope, for the location and extraction of trapped victims. Safety lines are used during the penetration of the rubble and are overseen by the TF safety officer.

US&R Task Force Deployment

The US&R TF is designed to optimize the search and rescue capability of a disaster response operation. To

achieve that goal, the team must be rapidly deployable, self-sufficient on arrival and for 72 hours, and possess specialized personnel and equipment. During a deployment, the TF will operate 24 hours a day, rotating its personnel in 12-hour shifts. The 28 US&R TFs in existence are regionally dispersed so that the likelihood of one or more TF being in close proximity to a disaster and able to be on-scene as quickly as possible is increased. Table 40-1 shows the distribution of these teams by state.

On arrival, the TF integrates into the ongoing response operation and into the Incident Command System. Because US&R TFs are rapid-deployment assets, they do not carry heavy machinery to the site. Initially, engineers on the team will assess the site and make determinations as to the equipment and specialty needs. If there is a requirement for heavy equipment, such as ground-moving bulldozers or heavy cranes, the logistics officers, who are a part of the technical team, will begin to liaison with local vendors of such equipment. These same logistics officers, much like in other specialized disaster response teams, will look for caches of food, water, fuel, and other essential supplies to maintain the team on site beyond the initial 72-hour supply the team carries with it.

Each disaster is unique, and the availability of resources is equally different. In urban settings, there is a higher likelihood of obtaining necessary supplies in a timely manner, whereas in more rural settings this task may be a complicated one. The enormity of the tsunami that struck the vast area around the Indian Ocean in 2004 demonstrates the potential difficulties faced by search and rescue teams. The logistics of obtaining necessary equipment and supplies in very rural settings, such as those areas struck by the tsunami, can be an extremely difficult and mission-limiting process. Conversely, after the 2001 WTC attacks, there was a tremendous outpouring of food and supplies into the

TABLE 40-1 DISTRIBUTION BY STATE OF URBAN SEARCH AND RESCUE TASK FORCES

NO. OF USAR TFs	STATE

1	Tennessee
1	Texas
1	Utah
2	Virginia
1	Washington

site. This overabundance of resources can create a logistical problem as well, simply due to the effort required to manage them. There were incidents weeks into the WTC disaster response in which large food stores were becoming rancid, causing a risk of rodent infestation and subsequent infectious disease outbreak. In addition, large numbers of supplies and resources can strain an Incident Command System in a large-scale disaster that is already having difficulties controlling the extent of the response.^{5,6} In such scenarios it is important for US&R logistics personnel to ensure that appropriate equipment and supplies specific to the disaster are being obtained and that those supplies are being managed effectively throughout the duration of the deployment.

Search and Rescue Operations

There are five stages to a US&R operation: reconnaissance, assessment of any victims present, detailed search of areas with higher probability of live victims, guided small-scale debris removal, and large-scale debris removal. The first two stages are surface operations only designed to gain knowledge about the rubble pile and to look for victims lying on or near the surface. The last three stages involve penetrating the pile; locating, treating, and removing victims; and removing debris.

Immediately on arrival, as the logistical operation to maintain a safe and self-sufficient presence is under way, the search and rescue stages of operation begin. The search and rescue specialists obtain blueprints of any involved structures from local resources (before arriving on-scene if possible) and begin to devise an approach into the collapsed structures. These blueprints can be invaluable for determining where the rubble may require shoring up and where the potential collapse hazards exist. In addition, it may be possible to identify safe havens where trapped victims may have congregated.

Soon after arrival, a preliminary search by search and rescue specialists takes place. This involves a cautious probing of the surface of the structure and is designed to both develop a working knowledge of the details of the collapsed structure and to attempt to quickly identify trapped victims so that rescue can be accomplished as early as possible. This initial search is typically not done with cameras or dogs and is a relatively superficial one. After the initial search, more formal search and rescue operations begin. During this part of the operation, all resources available to the team are brought into use. The process is much like peeling an onion. The teams must probe and remove debris from the top of the rubble pile down, thereby minimizing the possibility of further collapse. An area to be searched will be identified and the parameters of the search determined. As US&R specialists probe the rubble, "bucket brigades" are set up to remove debris from the area. This is a slow process but is necessary because heavy machinery may disrupt an area and possibly cause secondary collapse onto workers or trapped victims. As an area is searched and the presence of live victims is ruled out, heavy equipment can replace bucket brigades so that rubble can be removed more rapidly. Care still must be taken with the heavy equipment because unexpected live victims may

be encountered. The safe removal of rubble from a search and rescue scene by heavy equipment is one of the most difficult operations faced by the task force.

As victims are located, a series of steps is taken to assess their medical condition, ensure their safety, and effect their extrication from the structure. A rapid triage-like assessment will be made of the victim's condition. If possible, vital signs will be taken and the victim will be asked a series of questions concerning the extent of his or her entrapment and level of pain and the possible presence of other survivors. Treatment may be started while the victim is being extricated from the structure.

Confined Space Medicine

The medical care of victims entrapped in debris has become an area of great advancement in search and rescue technique over the past decade. With improved search and rescue capabilities came the discovery of victims still alive for days, and rarely more than a week, after a disaster event. This led to the development of an area of medicine studying the care of these victims while still trapped in the rubble and immediately thereafter.

Victims trapped in small, confined spaces pose a considerable challenge to the rescuer. Such spaces are prone to threats affecting both the victim and the rescuer, such as collapse, hazardous materials and gases, temperature extremes, electrocution, and lack of oxygen.⁷ These inherent hazards make the extrication and medical care of victims difficult and dangerous operations. Care must be taken initially to ensure that there is no risk of collapse of the space. A determination is made by rescue personnel as to the stability of the structure and the need for shoring up. All hazardous materials in the area must also be identified. Carbon monoxide is a common hazard in spaces where there may be fire, smoke, and operating equipment nearby. Detection of high carbon monoxide levels must be made early, and breathing equipment must be used by both rescuers and victims. Flammable gases also pose a significant threat in closed spaces. The likelihood of fire or explosion with flammable gases present is greatly increased in these spaces, where equipment such as welders and generators may be used. The presence of a flammable gas must be quickly recognized and appropriate steps taken to secure the safety of the area.

Once scene safety has been established and all hazards addressed, the rescuer will implement CSM techniques to care for the trapped victim. Concurrently, efforts will be made to extricate the victim from the scene. Initial assessment and treatment follow standard emergency care procedures, with the victim resuscitated if necessary and the most life-threatening injuries addressed first. The airway may be a difficult management concern for the medical team. Depending on how the victim is trapped and what kind of access there is to the victim, the rescuer may be forced to use unusual airway techniques, such as blind nasal intubation, digital intubation, or cricothyrotomy in suboptimal conditions. It is important, therefore, for the medical personnel to be trained and proficient in many different airway procedures. Clearly there are no

medical procedures that should significantly delay the extrication of the patient from the rubble, save for emergent airway intervention. During extrication, as in the management of any trauma patient, strict cervical spine and back immobilization is practiced.

Trapped victims may have a myriad of injuries secondary to the initial trauma or as a result of the prolonged stay beneath the rubble. In addition, infectious disease and hazardous materials exposure issues may arise as well. Each victim must be assessed and treated based on the unique circumstances to which he or she has been exposed.

Crush Injury and Crush Syndrome

One of the more common injury patterns seen in CSM is the crush-injured patient. These injuries are often present in victims of building collapse and earthquakes, in particular, and result from initial trauma and then prolonged time beneath heavy rubble. There are many similarities in both injury patterns of the victims and the immediate lay-person response seen in building collapse and earthquake disasters.⁸ In each type of scenario, the lay public in the immediate area often attempts to rescue trapped victims. Meanwhile, victims in both building collapse and earthquake scenarios who are trapped beneath heavy rubble for long periods can manifest crush syndrome.

Extrication of victims trapped under heavy rubble is a very difficult task that requires precision logistical planning for shoring up and evaluating the collapsed structure. Victims run the risk of further time beneath rubble, as well as the ongoing risk of secondary collapse. During the extrication of crush-injured patients, there is a period of high risk for sudden death when the heavy material is lifted off the patient. Known as the “smiling death,” the victim is typically awake and alert before extrication and then dies within minutes of the heavy material being removed.⁹

Crush injury and crush syndrome are two different entities. Crush injury is the result of direct trauma to a limb and the resultant injury to muscle, soft tissue, and bone. Crush syndrome is secondary to muscle death and the subsequent electrolyte fluxes, third spacing of fluid, and rhabdomyolysis that occur.¹⁰ Death of limb musculature can occur as early as 1 hour after significant trauma or hours later. This leads to necrosis and subsequent breakdown of muscle, causing a release of intracellular contents into the plasma. Therefore, the extent of crush syndrome is directly related to the amount of musculature injured and the time spent under the rubble.¹¹ These intracellular contents remain localized and build along with lactic acid as more and more muscle dies. The release of these substances into the bloodstream when the limb is freed results in their recirculation. The rapid death seen in some of these cases is thought to occur from cardiac arrhythmia induced by high concentrations of intracellular electrolytes, such as potassium, suddenly bathing the heart.¹² In addition, rhabdomyolysis, which is seen in crush syndrome, often leads to acute renal failure. In both the Armenia and Marmara earthquakes, crush syndrome and acute renal failure were seen in a

large number of victims who were rescued alive from the rubble.^{13,14}

The treatment of crush syndrome involves intravenous hydration, early hemodialysis, and supportive care. The victim will require large amounts of intravenous crystalloid; this therapy should be started as early as possible. If the victim is trapped and unable to be removed immediately, he or she should have an intravenous line placed while in the rubble, if possible, and rehydration should begin before extrication. Early administration of crystalloid will minimize the occurrence of acute renal failure. The victim's limb must also be monitored for the development of compartment syndrome secondary to limb swelling. Some suggest performing fasciotomy if compartment syndrome is suspected.¹⁵

Field limb amputation has long been a hotly debated topic in the search and rescue literature. The need for such drastic action is rarely ever considered and has as its only real indication the inability to remove a victim from entrapment when either the scene is becoming unsafe or the patient's medical condition is rapidly deteriorating. The decision to perform field amputation of a limb is one made by the medical team, as part of the US&R TF, under consultation with the rescue personnel. If done, attention must be paid immediately to the control of blood loss and the quick removal of the patient to more definitive care.

Confined Space Medicine Injuries

There are a number of other injury patterns typical in CSM and, therefore, seen in US&R operations. These also present unique obstacles to the US&R medical teams, and the care of such victims requires specialized knowledge and skills. The cause of a building collapse may dictate the type of injuries seen. For instance, a collapse due to loss of structural integrity during an earthquake is quite different from a collapse secondary to an explosion. With the heightened concern of terrorist events today, the latter is more and more a possibility.¹⁶ As an example, in the WTC and Pentagon attacks of Sept. 11, 2001, airliners acting as flying explosive devices assaulted the towers. The airplanes exploded on impact. Victims in the immediate area were first traumatized by the explosion and subsequent blast effect, fire in and around the impact zone, and finally the collapse of the structure. Had there been survival of victims from within the collapsed structures, multiple injury patterns would have been seen.

It is not uncommon for victims trapped under rubble to have experienced blast injury from the initial event.¹⁷ Blast injury results from differing effects caused by varying features of the explosion. Blast injury can be divided into four phases: primary, secondary, tertiary, and quaternary. Primary injury pattern is a result of the blast wave created by a high-order explosive, such as ammonium nitrate, creating a super-sonic explosion. This is an over-pressurization wave and causes injury and rupture of hollow, air-filled organs, such as lungs, abdominal luminal organs, and eyes. Secondary blast injury occurs from the flying debris generated by the explosion and can injure

any part of the body with shrapnel. Tertiary blast injury is the result of the victim being thrown by the explosion and subsequent blunt and penetrating trauma. Finally, quaternary blast injury is “everything else” and includes such things as structure collapse.¹⁸ An understanding of these stages of blast injury and their causes enables the US&R medical teams to predict injury patterns and treat them more effectively.

Prolonged entrapment under rubble may also cause a number of syndromes similar to those seen in patients suffering from exposure. Depending on the amount of time and the conditions under the rubble, victims may have a myriad of exposure syndromes such as hypothermia or hyperthermia, dehydration, starvation, or infection.¹⁹ These syndromes should each be addressed based on their presence at the scene as early as possible. If possible, intravenous lines should be placed and crystalloid hydration begun vigorously if the victim is entrapped and accessible. Warm air and space blankets can be used to counter hypothermia, and nourishment in the form of portable foodstuffs can be administered. The greatest obstacle to the care of these victims is not anticipating the occurrence of these injury states.

PITFALLS

1. It is essential for disaster response specialists to have a working knowledge of the US&R TF makeup and procedures. Not doing so may cause a breakdown in the incident command and disaster response systems.
2. Understanding the pathophysiology of crush syndrome is paramount to the care of entrapped victims. The disaster medical specialist working with US&R assets should be prepared to care for victims with crush syndrome both at the scene and in emergency departments
3. Having a working knowledge of the myriad of injuries that result from structure collapse and victim entrapment will allow the disaster medical specialist to align resources and prepare to receive such casualties. This will, in turn, result in better outcome through more efficient care.

Medical Care in Remote Areas

Thomas P. LeBosquet III and David E. Marcozzi

Webster's Dictionary offers one definition of "remote" as simply "out-of-the-way." This clarifies the feelings we have connected to this word, but it does not provide an adequate definition in relation to modern medical care. The reality is that "remoteness" covers a vast spectrum. Traditionally, emergency medicine has come to define remoteness as being linked to the time to care. Concepts such as the "golden hour" have sprung from this.¹ In other words, an hour is entirely too long without care to save a patient in need of certain care such as airway management or defibrillation. Over 222 million of the current U.S. population lives in urban areas, whereas only 59 million (21%) live in rural areas.² Because of this and the increasing centralization of medical centers within the United States, there has been an increasing need to provide methods of stabilization and transport to patients in remote areas.

HISTORICAL PERSPECTIVE

Medicine has followed the continuum of society from agrarian, rural-based communities, with health care practiced by those indigenous to the area, to a technology-driven, urban-based society with health care dependent on major medical centers whose locations and practitioners remain remote to many people. Indeed, Mott and Roemer³ preface their 1948 work by stating: "The forces of social organization necessary to bring the average citizen the benefits of applied medical science have been strongest in the cities; the country dweller is last to be served."

Rosenblatt and Moscovice⁴ describe a five-step process in the evolution of rural health within the United States. The first, and longest, period covers Colonization to Industrialization (1620-1850). The need for healthcare beyond basic treatment was largely delivered by midwives, men with other professions (such as farmers, who would truly "moonlight" by doctoring on a part-time basis), or clergy devoted to their sect. The second period, Industrial Growth to the "Pre-Flexner Era" (1850-1910), marks the incorporation of science into medicine. The Civil War, advent of anesthesia, and development of sterile technique brought medicine to the point where general practitioners alone could no longer

master the entire scope of medicine. The third period stretches from the publication of the Flexner Report to World War II (1910-1940). The Flexner Report revolutionized the practice of medicine by shifting physician education from a venture to an academic affair.⁵ The fourth period moves toward the War on Poverty (1940-1970). Government programs aimed to increase hospital and medical care access. Hospital beds in rural areas were increased, but overall access to care changed little. The last, and current, period is the "Technological Era" (1970-present).

Current Practice

Physician distribution perhaps best illustrates the problems unique to remote areas. Metropolitan areas with populations greater than 1 million have 304 physicians per 100,000 population, whereas rural towns with populations below 2500 have an average of only 53 physicians per 100,000 population. Physician specialty largely determines the type of area chosen for practice. The greater the degree of subspecialization, the larger the area needed to support a practitioner. A family practitioner can run a viable practice with a patient base of 2000, but a single neurosurgeon requires a patient base of 100,000 to remain viable.⁶ Because of the need for 24-hour care and cross-coverage, it is impractical for those practitioners who are unable to treat both adults and children to work in certain areas. A population of greater than 10,000 patients, or at least five physicians, is needed before internists and pediatricians can be used well.⁶ Not only are generalists more likely to be found in rural areas, they are more able to fit the needs of those areas.

Over the past 50 years, a nationwide system of Emergency Medical Services (EMS) has developed. In 1966 the National Highway Safety Act brought structure to emergency care with the creation of the Emergency Medical Technician (EMT). These providers were trained to assess patients rapidly and transport them to a higher level of care. EMS has now evolved into a large network of systems designed to receive, stabilize, transport, and transfer patients to any level of care required. EMS transport systems allow major medical centers to expand their patient catchment area. For example, at

Duke University, the Life Flight system, a network of ambulances and several helicopters, allows expansion of a large tertiary care center to cover areas of North Carolina, South Carolina, Virginia, West Virginia, and Tennessee.⁷

Many organizations have developed specific criteria for transportation to a hospital for definitive care.⁸ When the decision to transfer is contemplated, the practitioner may use a two-step planning process. First, the patient's need for the services of medical and surgical specialties unavailable at the remote center must be assessed. Second, a prognostic view of the patient's overall condition and vital functions is made. The practitioner must ask: "Will this patient's airway deteriorate? Does he need to be intubated now to pre-empt complications in transport? Does he need a chest tube? Does he have sufficient IV access in case resuscitation is needed? Does he need any cardiovascular drips? What if he starts to bleed?" Anticipation of future complications is both the key criterion and caveat when preparing a patient for transport.

Practicing in remote areas means that preventive medicine is vital. Injury prevention can start simply and progress to the more complex. In an area with the potential for delayed access to medical care, injuries handled easily in one locale can become complicated in another. In many remote places, especially those with poor roads or no vehicular access, ambulation remains the main form of transportation. A simple ankle sprain, limiting the ability to walk, hinders activities of daily living and makes extraction to medical care tedious compared with vehicular transport. Minimizing risk is the important consideration of preventive health. Greater caution must also be taken with activities in remote areas. The healthcare practitioner must anticipate specific problems related to the environment that will be encountered.

Williams et al⁹ explain the realities of emergency medicine as it is applied in rural and remote settings. They first underline the point that rural emergency medicine is not exclusive to those trained as emergency physicians. Most small, rural emergency departments employ physicians who are neither residency trained in emergency medicine nor board certified in emergency medicine. Many emergency departments make use of family practitioners who practice exclusively in the emergency department or log extra hours outside their normal practice. Upward of 50% of emergency departments across the United States employ either nurse practitioners or physician assistants. Use of these resources may not be a negative. Because emergency medicine residencies are centered in urban areas, it is necessary to have training institutions make available resources for further education in emergency medicine such as publications for non-specialists and online continuing medical education.

Adaptability to unique situations and conditions is key to optimizing care in remote environments. The number of providers available and the experience of providers often vary. The healthcare team may consist solely of an individual with first-aid training who happens upon the victim, or it may be a complex web of physicians, nurses, rescue workers, and paraprofessionals working together

in a preorganized manner. For this reason the concept of a laterally moving hierarchy allows efficiency. In this structure a direct care provider may assume one or multiple patients. A team leader provides direction to providers so care may be coordinated between patients or that critical care may be provided to one patient. Support workers then help with both primary goals such as medical procedures and secondary goals such as reconnaissance of data and equipment, communication, and patient transport. This structure overlaps because the same individual, over time, may act as team leader, direct care provider, and support provider. Also, this structure may allow multiple leaders at multiple levels to provide coordination of care when a larger event occurs and multiple teams are needed (Fig. 41-1).

When preparing to work in a remote area for a significant time, adequate preparation is important. This mostly depends on the length of stay, the type and number of patients being seen, and the area. It may be as simple as a first-aid kit or as elaborate as a busload of supplies. One of the most challenging decisions is which pharmaceutical arsenal to bring. The World Health Organization (WHO) has labeled drug access, as well as the appropriate use, as a major priority. WHO has clearly defined a list of essential medications that "satisfy the priority healthcare needs of the population."¹⁰ These medicines are chosen because of the diseases they treat, their availability, and their prices.

Pitfalls

Several models have been attempted to bring healthcare to truly remote areas, such as rural areas in developing nations. When the population of an area exceeds the need for multiple physicians or is lower than needed to support one physician, a traveling clinic may be one solution. The government of Uttaranchal, India successfully launched such a program. They use a 26-foot mobile clinic created from a mobile home that brings physicians to different areas 4 days a week with return visits monthly. This mobile clinic contains the diagnostic equipment to perform EKGs, some basic laboratory testing, radiographs, and even ultrasound.¹¹ It is unique in that it provides general healthcare; previous mobile clinics in that area provided only specialty care. It serves as a model for an expanding program. Similar mobile clinics have been started in Central America and have also found success.¹²

Unusual troubleshooting is necessary in remote areas. For example, a high percentage of visitors to New Hampshire's White Mountains seek outdoor recreation. A 25-year-old female takes advantage of a warm winter day and, with one of her college friends, hikes 4 miles inward on Mount Washington to get in some great ice climbing in the Tuckerman Ravine area. After several hours of easy climbs she decides to lead a challenging route by early afternoon. Unfortunately, with her last piece of protection 15 feet below, she realizes the afternoon ice has become soft. Now 30 feet above her belayer, she loses the grip with her crampons, slips and falls that distance to land feet first, and shatters both of her ankles. Upon impact she bounces backward and

FIGURE 41-1. Proposed laterally moving structure for care provision in remote areas. It is important to recognize team members can play different roles depending on the situation, location, total number of workers available, and the acuity of the patient. This pattern may also be used in a repeating structure when multiple teams are needed.

thrusts the pick of her ice ax through the left lateral aspect of her chest wall. Within seconds she is now immobile and has a pneumothorax. She was wearing her climbing helmet and is conscious. Her climbing partner, who took an EMT class, knows how to assess her ABCs. He does not have a stethoscope or blood pressure cuff, but he is able to measure that her heart rate is 95. He uses the sling in his first-aid kit and extra clothing in her backpack to stabilize the wound from the ice ax. A climber with another group, who has run over to help, runs to the hut halfway up the trail to use the radio that is there because his cellular phone is not receiving any signal. She has begun complaining that her foot is starting to hurt, but also that it is “falling asleep.” Now, what to do with this patient? There are several details of her situation that could compromise her care. She is now sitting, with multiple life- and limb-threatening injuries, in cold snow. Although it is a warm day at 40° F, it is 2 PM and the sun will be going down at 4:15 PM. If the wind picks up, the temperature could easily drop to -10° F overnight. Not only is the stationary patient, whose sweat-soaked clothing will freeze when the temperature drops, at risk, but any potential rescuers would also be at severe risk of hypothermia and cold injuries. It would take hours for the 18 or so people who would be needed to litter out this patient to arrive. She will need to be airlifted; however, she has a pneumothorax. If she did not have a chest tube placed before being carried in the aircraft, her stable pneumothorax could rapidly expand to become a tension pneumothorax. When the helicopter arrived, the rescue team would need the supplies, as

well as a capable practitioner, to place the chest tube. Where would this patient need to be transported? The nearby community hospital has amassed an excellent collection of orthopedists because of the local ski areas and their associated injuries. They could handily repair her fractures and relieve her compartment syndrome. However, there is no thoracic surgeon nearby to remove the ice ax perched dangerously close to her pulmonary vasculature. She would need to be transported to a large medical center, which by land would be 2 hours east, 2 hours west, or 3 hours south. Assuming good weather, airlift would reduce these times because much of the land transport time is exacerbated by small rural roads.

This example should illustrate that providing medical care in remote areas requires the coordination of both practitioners and resources. The needs for these are unique and dynamic, and they depend on patient, disease, and location.^{13,14}

SUMMARY

The main points of this chapter are as follows:

1. Healthcare has long been practiced in remote areas.
2. Those traveling through or living in remote areas ultimately will receive care from someone.
3. The practitioner must appropriately mix technology-based care and more traditional physical examination and observation-based techniques when technologies are not available.

4. Each remote setting and situation is different. Care must be tailored to the patient, disease, environment, and resources.

EMS Beyond the Barricade

Louis N. Molino, Sr.

The title of this chapter refers to the EMS operations on the “hot side” of a barricade in response to incidents that involve hazardous materials (also referred to as *HazMat incidents*). The single best working definition of HazMats is when materials released from their containers can and do cause harm to both humans and the environment.¹

WHERE HAZARDOUS MATERIALS INCIDENTS OCCUR

The more times a hazardous material is handled or manipulated, the more opportunity for an incident to occur. Because of public opinion, legal pressure, and potential litigation, the chemical manufacturing and transportation industries have recognized the need for due diligence in care of these materials throughout the chemical life cycle (see following text). These societal pressures and industry responses have decreased the number of incidents over the past several years.²

Responders are often surprised with the numbers and types of chemical operations present in the community.³ HazMat incidents can occur at every stage of the chemical life cycle, and emergency response forces must be ready to respond to each of these stages⁴:

- Research and development
- Site of manufacture
- Storage (at site of manufacture)
- Transportation
- Storage (at site of use)
- Site of use
- Disposal of waste product

Research and Development

The research and development phase of chemical operations is often one of the most dangerous and is generally undertaken only under extreme safety procedures. Most of the research conducted in the United States is in an academic setting or at dedicated research facilities. These facilities often have their own emergency response capability on-site.⁵

Communities hosting such facilities often meet with the management of the facility to understand the nature

of the on-site research. This may conflict with legitimate concerns of industrial espionage. Although chemical producers would be willing to discuss any of their work, they may not be willing to discuss details of their ongoing research. These facilities often have plans that are integrated with the local response community to manage emergencies.⁵

Manufacture

The manufacturing process presents the greatest bulk hazard because materials are stored, handled, and mixed at the facility throughout the process. This is also where industry has focused their prevention efforts. Billions of dollars are spent by the chemical industry to prevent incidents or to limit the incident to the plant itself.

In many manufacturing plants, the hazardous materials response capability may be more robust than the local public capability. The local community may be able to draw on these abilities to augment its own response for off-site accidents that occur. This requires preplanning with the plant to determine how the plant can support the public sector response forces and vice versa.^{5,6}

Storage (at Site of Manufacture)

Many manufacturing sites store quantities of materials prior to shipment on the same sites as their manufacturing operations. A complete understanding of the nature of the products stored and their associated storage systems for each facility is necessary for emergency response forces. Preplanning is essential for the successful response and operations at bulk storage sites of any type.^{5,6}

Transportation

Ultimately all products that are manufactured will be moved to their end users. During transportation, the chemical industry has less control and oversight because of road, weather, and other conditions. Because the incident may occur at any point of the transportation phase, available resources from the chemical company may be far removed from the incident.^{5,6}

Storage (at Site of Use)

The nature and types of risks at this point are wholly dependent on the quantity of materials stored and how they are stored. If a quantity of materials is stored on-site, which could present a serious response problem for local emergency forces, preplanning and mutual aid as well as preincident interaction with the chemical producer and user is paramount in order to ensure that all safety precautions are in place.^{5,6}

Use

In the use phase, the element of human error predominates. The unintentional or even intentional misuse of chemicals has always plagued emergency response forces. The threat of the intentional misuse of chemicals as “agents of opportunity” is something that emergency planners should consider.^{5,6}

Disposal of Waste Product

The final phase of the chemical life cycle is the disposal phase. The disposal phase has an increased potential for a serious incident. With some materials the breakdown products may be more hazardous than the original product itself. In these cases disposal procedures may become complicated.

For most wastes, specific regulations exist to ensure the proper disposal of such products. In the past, large hazardous waste dumps could be found all over the United States. Many have lingering health effects that have plagued the host communities for decades. Cleanup for these sites may cost millions of dollars. Emergency response may be initiated for a previously unknown site when its effects are noticed.^{5,6}

HOW HAZARDOUS MATERIALS HARM HUMANS

The three main mechanisms of harm in the case of chemical emergencies are as follows^{3,7-10}:

- **Flammability:** Causing thermal injury such as burns and scalds
- **Reactivity:** Causing a rapid release of energy when a chemical reaction occurs
- **Health effects:** Causing the disruption of normal bodily functions

These mechanisms can lead to severe physical trauma (e.g., burns, penetrating and blunt force trauma from the resultant fires, explosions, and other physical means). These injuries are often complicated by the toxic properties of the chemical

Hazardous chemicals can interact with the human body in four routes of exposure:

- Inhalation
- Absorption
- Ingestion
- Injection

HAZMAT BEHAVIOR

Hazardous materials are chemicals that follow the laws of physics and have generally easily predictable properties. By understanding the laws of chemistry and physics, responders can avoid exposure and effectively respond to and mitigate the hazardous materials emergency.^{1,6}

Accidental HazMat incidents occur because of one or more of the following initiation events¹:

- Human error
- Environmental conditions
- Container failure
- Equipment failure

When one or more of these initiators occurs, the hazardous material is released into the environment. A sequence of events known as the Six-Step General Events Behavior Model occurs, which was first described by Ludwig Benner, Jr. in his classic 1978 work, “A Textbook for Use in the Study of Hazardous Materials Emergencies.”¹¹ These six steps are repeated in every incident in which hazardous materials are released into the environment. The six steps are:

- **Stress:** Something stresses the container
- **Breach:** The container is breached
- **Release:** The material in the container is released into the environment
- **Engulfment:** The material spreads into the environment
- **Impingement:** The material that has spread comes into contact with people or other exposures to which harm may occur from the resultant contact with the HazMat
- **Harm:** Harm comes to the living things from the hazardous material

Each of these events must occur in the order described; however, they can occur in rapid succession. The time depends on the nature of the event and the materials and containers involved in the incident.¹¹

HISTORICAL PERSPECTIVE

Hazardous materials are among the tools that allow us our modern life. Use of hazardous materials in construction, manufacturing, and fabricating predates the Roman civilization.⁵ Since their first use there have been incidents that have caused harm to both humans and to the environment. During the 1960s a number of significant hazardous materials incidents focused public attention on the problems associated with the manufacture, storage, transportation, use, and disposal of such materials.⁵ Until the late 1970s, few training courses were offered to the fire, police, and EMS community.¹² Most incidents were managed by the local authorities as best as possible, frequently (and poorly) by EMS teams.^{13,14} Several incidents made the EMS community painfully aware of the need for both special training and tactics for response to these types of incidents.⁵ There was also the need for special care for the victims of these incidents.^{3,7-10}

Training courses on handling of hazardous materials at all levels of proficiency are readily found throughout the United States.^{14,15}

Most EMS agencies are ill equipped and poorly trained to respond to HazMat incidents. Even those that may be a part of the fire department system in their community often lack the level of training or the level of preparedness. With the recent influx of funding for local agencies to prepare for weapons of mass destruction (WMD) on a national level, the proficiency of many local fire and EMS agencies to manage “everyday” HazMat incidents has also improved.

CURRENT PRACTICE

All responders are required to meet or exceed the training recommendations of the Occupational Safety and Health Administration (OSHA) regulations found in 29 CFR 1910.120 (q) (6)¹² the standard for HazMat responders. Furthermore, all responders should strive to meet all of the requirements at a minimum of the Operations Level of the National Fire Protection Association (NFPA) 472,¹⁷ the Standard for Professional Competence of Responders to Hazardous Materials Incidents. Doing so ensures that the responders have acquired the necessary knowledge, skills, and abilities needed for a safe response to incidents involving hazardous materials.

Hazardous Materials Incident Response

A hazardous materials response may be initiated for any incident that has a HazMat presence. Incidents resulting in small spills of common hazardous materials are not likely to initiate a HazMat response in most jurisdictions. If the quantity of a hazardous chemical exceeds the local response capability, a HazMat emergency may be declared.¹⁷

It is difficult to describe a typical HazMat response in the United States as various jurisdictions have established procedures that vary as widely as the response community itself. Until recently ambulances would be dispatched in the course of HazMat response, but the responding personnel would have little or no specialized training and no protective equipment. That has changed significantly over the past decade.⁴

All personnel who may respond to a HazMat incident require training. The level to which personnel are trained may vary within an agency based on assignment and expected duties, but, by federal law, all training must meet certain levels of knowledge and skills as set forth in OSHA 29 CFR 1910.120 (q) (16) as well as NFPA 472. The levels are referred to as Awareness, Operations, Technician, Specialist, and Incident Commander as defined below¹⁶:

Awareness Level

First responders at the awareness level are individuals who are likely to witness or discover a hazardous substance release and who have been trained to initiate an

emergency response sequence by notifying the proper authorities of the release. They take no action beyond notifying the authorities of the release.

Operations Level

First responders at the operations level are those who respond to releases or potential releases of hazardous substances to protect persons, property, or the environment from the effects of the release. They are trained to respond in a defensive fashion without attempting to stop the release. They will attempt to contain the release from a safe distance, keep it from spreading, and prevent exposures.

Hazardous Materials Technician

Hazardous materials technicians respond to releases or potential releases to stop the release of the hazardous material. They approach the point of release in order to plug, patch, or otherwise stop the release of a hazardous substance.

Hazardous Materials Specialist

Hazardous materials specialists respond with and provide support to hazardous materials technicians. Their duties parallel those of the hazardous materials technician, although those duties require a more directed or specific knowledge of the various substances they may be called on to contain. The hazardous materials specialist would also act as the site liaison with federal, state, local, and other government authorities in regard to site activities.

Hazardous Materials Incident Commander

Incident commanders, who assume control of the incident at the scene, receive at least 24 hours of training equal to the first responder operations level and are able to implement the incident command system and the appropriate site, local, regional, and federal emergency response plans.

Once trained, the maintenance of that training and the exercising of both the knowledge and skill components of the training become paramount to ensure competence and the ability to respond both safely and effectively. The incident commander is ultimately responsible for the safety of all responders and victims on the incident scene.

Decontamination

If the contaminant is such that the rescuers could become harmed by the substances that are on the patient, the treatment of that patient should be delayed until the threat is neutralized. In all other cases, the patient's care becomes the first priority.

The generally accepted method of decontamination for most substances is water. Although many types of homemade and commercially available decontamination formulas and units are available, the nozzle of a fire hose

is generally the fastest means of delivering the water to the victim and is generally the most rapid form of decontamination available.

Assessment of the HazMat Victim

The assessment of a HazMat victim begins with the rapid and accurate identification of the substances involved in the incident. A methodical assessment of the patient should take place.^{4,8,10}

HazMat Physiology and Treatment Protocols¹⁰

Many antidotes and specific treatment protocols exist for the treatment of chemical exposures. Some are appropriate for prehospital use, whereas others will be performed only in the clinical setting.

Some of the chemicals with specific antidotes or treatment protocols include:

- Cyanide and cyanide compounds
- Hydrofluoric acid
- Aniline dyes
- Nitrites
- Nitrates
- Nitrobenzene
- Nitrogen dioxide
- Organophosphates
- Carbamates
- Phenol
- Chlorine
- Chloramine
- Common lacrimators such as OC spray and mace

Many HazMat teams and their medical personnel carry a HazMat drug box containing medications beyond the normally carried ALS drugs. Some medications in the HazMat ALS drug box may include the following¹⁰:

- Adenosine
- Metaproterenol (inhaler/nebulizer package)
- Amyl nitrate perles
- Atropine sulfate (often as prepackaged auto injectors)
- Esmolol (Brevibloc)
- Calcium gluconate
- Dextrose 5%
- Dextrose 50%
- Diazepam
- Dopamine
- Epinephrine
- Methylene blue
- Naloxone
- Albuterol
- Pontocaine hydrochloride
- Pralidoxime (2-PAM often carried as prepackaged auto injectors)
- Sodium bicarbonate
- Sodium nitrite
- Sodium thiosulfate

- Thiamine
- Morgan irrigation lens

The specific concentrations and quantities carried vary based on local medical direction and/or state protocols.

Responder Protection for HazMat Response

The most important factor in response to HazMat incidents is self-protection.^{17,19,20} The first principle is to avoid contact with any hazardous materials.¹⁷ This requires basic understanding of the chemical and physical properties of the materials involved in the incident. Further protection is provided by wearing specific personal protective equipment (PPE).

There are four recognized levels of personal protection for HazMat incidents.¹⁶ These four levels of protection are based on the following concepts:

- No one glove, boot, or splash suit is omnipotent in protection qualities
- The ensemble is selected based on an analysis of the work to be performed and the hazards likely to be encountered.

The levels of PPE are known as Level A, B, C, and D, and they are described in OSHA, EPA, and NFPA standards in the following basic terms¹⁷:

- Level A: Full-body vapor proof suits with self-contained breathing apparatus (SCBA) for respiratory protection
- Level B: Full-body protection that is splash resistant with SCBA for respiratory protection
- Level C: Splash protection with chemical-resistant boots and gloves and use of an air-purifying respirator for respiratory protection
- Level D: Normal work uniform

OSHA mandates that training be given to any responder who will be operating in any level of protection. OSHA further mandates that those with the responsibility of determining what specific PPE is to be used on a given response be specifically trained in both the selection process and risk analysis.¹⁶

PPE usage is a skill that must be practiced. Classroom training alone is not sufficient to ensure that a responder has the skills to use PPE in the hazardous environment found in a HazMat response. Only training and practice can ensure that this skill set will be available during an actual emergency.

Medical Support of the HazMat Team in Incident Operations

One role for the HazMat medical personnel is to support the efforts of the HazMat team as it operates. The use of PPE alone is potentially dangerous, particularly in hot climates. Therefore, even in drills or exercises the availability of HazMat-trained medical personnel ensures the safety of the responder.⁶

PITFALLS

The hazards are based on the chemicals encountered. This can present a problem where the chemicals are not immediately known. In such circumstances the incident commander determines what level of protection and what components of the PPE ensemble are to be used by responders.

CONCLUSION

HazMat operations are rife with risk, but, with proper training and equipment, HazMat teams are able to manage the hazards presented by such incidents on a daily basis. When people are harmed by these materials, EMS beyond the barricade is often the difference between life and death.

Triage

Andrew Reisner

"The train was cut open like a can of tuna. We didn't know who to treat first. There was a lot of blood, a lot of blood."

Enrique Sanchez, Madrid EMS, of simultaneous commuter train bombings, March 2004¹

Triage is the utilitarian sorting of patients into categories of priority to rationally allocate limited resources; it is, proverbially, to do "the greatest good for the greatest number." Triage fails in one of two ways: undertriage and overtriage. Undertriage represents a failure to identify the casualties who could benefit from scarce medical resources, such as the serious casualty whose life would be saved decisively with rapid evacuation and prompt emergency surgery. In terms of test characteristics, undertriage means poor sensitivity to those who would get the most benefit from the medical resources available. On the other hand, overtriage occurs when casualties who, relatively speaking, do not benefit from a scarce resource nonetheless receive that resource. Overtriage signifies a sorting system with low specificity. Noncritical patients who receive immediate care even though they could safely wait (at the expense of more serious, savable casualties) constitute one form of overtriage. It can also occur when expectant patients, so sick with little chance of treatment success, are provided with precious medical resources.

Triage following disaster is not a single processing step; rather, triage underlies all aspects of the response, including on-site rescue, evacuation, receiving hospital activities, decontamination, and so on. Because the response resources available, the clinical conditions of casualties, and the information available all evolve throughout the time-course of the response, response priorities do so as well. Triage is a dynamic process.

Disaster responses have been suggested to match normative practice as much as practically possible,^{2,3} and that, of course, would apply to triage methods. On the other hand, normative practice could pose a liability for massive disasters, in which a set of reflexes could interfere with the truly rational allocation of resources. This trade-off is discussed throughout this chapter. As noted in the following section, many recent disaster responses have been characterized by a general lack of meaningful triage.

HISTORICAL PERSPECTIVE

The roots of disaster triage stretch back to at least eighteenth-century military casualty care. Baron Larré, a surgeon with Napoleon's army, was utilitarian in his methods of managing multiple battlefield casualties, as was the American John Morgan during the U.S. Revolutionary War.⁴ Military triage evolved sporadically, but by World War II a hierarchical structure for combat casualty care had been developed. In WWII, the average time from injury to definitive care was 12 to 18 hours. By the Vietnam War, improved triage and air-ambulance capabilities reduced this time to less than 2 hours.⁵ This early military history of triage was reviewed nicely by Kennedy.⁴

In the 1980s, civilian prehospital systems became interested in trauma triage for the individual trauma casualty; West⁶ showed that serious trauma casualties had superior outcomes when cared for at specialized trauma centers. There were investigations of prehospital criteria for differentiating individual casualties that should be taken to major trauma centers and those that could receive care safely at community medical centers (to avoid overburdening trauma centers with non-serious casualties). Trauma registries enabled the development and validation of various field triage decision-rules, although such criteria have proven problematic (see the Triage Scoring System section). Such civilian trauma scoring in turn influenced modern military triage. In the 1991 Persian Gulf War, Burkle et al.⁷ explored the use of Champion's revised trauma score⁸ for triage of 461 combat casualties. Triage classification schemes for military and civilian mass casualties, to a large extent, have converged. Both military (e.g., NATO) and civilian (e.g., color coding) triage systems make use of comparable levels of acuity, and the Trauma Sieve and START, which are similar triage decision systems, are used by both civilian EMS as well as British Army soldiers.⁹

Regarding civilian triage, the past 25 years have seen a long litany of horrible events in industrialized countries,

including bombings, fires, shootings, and plane crashes.¹⁰ These events show a consistency of scale, with immediately surviving casualties numbering in the dozens or hundreds. Too many retrospective reports noted unsatisfactory execution of triage, particularly prehospital triage, for these events. In the mid-1980s, Vayer et al.³ cited Butman's analysis of 51 mass-casualty incidents (MCIs) that identified a universal failure to execute proper triage. Inadequate prehospital triage continues to be reported following MCIs: an aircraft crash in Singapore in 2000,¹¹ the Tokyo Sarin attacks,¹² and the Gothenburg fire disaster.¹³ Typically, documentation of prehospital triage during an MCI is quite poor, so retrospective analysis of field triage is simply not feasible, as was the case for the Oklahoma City bombing.¹⁴

The urban community in a developed country may very well possess the necessary resources to treat dozens or even hundreds of casualties, provided the resources are mobilized and the patients in need of immediate care are identified in a timely fashion. Yet suboptimal use of available community resources is the rule rather than exception; for instance, most casualties self-transport to the closest hospital and leave distant facilities underused.¹⁵ Community resources such as urgent care centers and outpatient clinics, capable of treating the majority of casualties with relatively minor issues, are almost always underused. Almogly et al.¹⁶ reported on the Israeli response to the Jerusalem Sbarro pizzeria bombing in 2001, and observed "in these circumstances [e.g., a mass casualty incident such as a suicide bombing], ordinary hospital resources are heavily burdened, yet delivery of efficient medical treatment is possible by recruitment of all available personnel and resources." In contrast to the many reports of poor triage after disasters, exemplary responses to MCIs have stemmed from exemplary mobilization of resources. After the bombing at Atlanta Centennial Olympics, 30 EMS units evacuated all 111 casualties to area hospitals within 32 minutes. The vast majority of serious casualties were taken to Grady Memorial Hospital where "at one point, there were more physicians than victims in the emergency care center"¹⁷ Those casualties all had good or excellent outcomes. After the Jerusalem Sbarro pizzeria bombing the prehospital response was largely "scoop-and-run." The Ein Kerem Campus, receiving 132 surviving casualties, performed two ED thoracotomies, with no apparent shortage of resources available for those less-critical casualties.¹⁶ Almogly's dictum pertains to most recent disasters in developed countries, which have been limited to dozens or hundreds of casualties. Popular field triage systems (see the Triage Scoring Systems section) are most appropriate for such scale of events.

On the other hand, such triage systems are less applicable to disasters with enormous scales. Counting the 1918 Influenza Pandemic and Hurricane Katrina in 2005, there have been only nine non-military disasters in the entire history of the United States that resulted in more than 1000 deaths. Internationally, massive disasters have produced tens or hundreds of thousands of dead and injured, such as earthquakes in Tangshan (1976), Armenia (1988), Hanshin-Awaji (1995), and Iran

(2003), as well as the Indian Ocean tsunami (2004). Field triage systems tend to be sensitive and not specific, leading to overtriage. More importantly, they may be too unwieldy to triage massive numbers of casualties. Moreover, they are tailored to traumatic pathology, although broad medical pathology (e.g., infectious disease, metabolic disarray) occurs in the aftermath of these massive disasters and baseline medical emergencies (e.g., heart attacks, tubal pregnancies) continue to occur unabated. Only a minority of emergency department patients were trauma victims following disasters such as the Loma Prieta earthquake and Hurricane Gloria.^{18,19}

To the extent that one seeks historical guidance when planning for the future, the emphasis that should be given to preparing for enormous-scale disasters in the United States is unknowable. Such events are so rare that we have little experience to guide us. (Traditionally it has been difficult to find the resources—funding, time, materials—to develop and maintain extensive skills and preparedness.) Similarly, respected authorities have suggested that too much attention has been paid to the unprecedented scenario of weapons of mass destruction (WMDs). Frykberg¹⁰ wrote: "We must resist our current tendency to become overly enamored with the 'weapons of mass destruction' of biologic, chemical and radiologic attacks, in terms of funding priorities and resource allocations that are wholly disproportionate to the clear reality of the terrorist bombing threat." History shows that smaller, more mundane mass casualty incidents must be anticipated, although arithmetic shows how one single WMD event could dwarf the sum of preceding MCIs in morbidity and mortality. In support of Frykberg's position, until emergency systems prove capable of triaging events with dozens or hundreds of casualties, does it make sense to prepare for an unprecedented event with thousands of casualties?

CURRENT PRACTICE

This section offers a technical framework for triage following a disaster. The issues discussed here are important to consider for disaster planning and training (and real-time execution), but the reader must always bear in mind those sobering limitations of triage systems detailed in the previous section. All the same, triage should be carried out to the extent possible at the scene and at every facility and site providing disaster care. Box 43-1 lists considerations that should be made in advance of any disaster. Box 43-2 lists details that need to be determined in real time after a rapid survey of the

BOX 43-1 TRIAGE PLAN PREPARATION (TO BE DETERMINED BEFORE ANY DISASTER)

- What triage classification is used, if any (e.g., four or five levels of severity)?
- Will a formal triage scoring system be used?
- What on-site/hospital documentation will be used?

BOX 43-2 TRIAGE PLAN DETAILS (REQUIRES SURVEY OF SPECIFIC DISASTER SITE)

- Who will be the triage officer(s)?
- Who will collect vital signs for the triage officer(s)?
- Physically, where will casualties from each triage category be treated (and who will staff each area)?
- What overtriage and undertriage rates are acceptable?
- What level of casualty gets “black-tagged”?
- Assuming 10 patients in 20 minutes per triage officer,¹⁷ are there enough officers?
- Are there enough other personnel to keep up with the triage team (e.g., litter bearers, care providers); if not, is the triage team too big?
- Are resources being used appropriately, including (a) on-site medical interventions, (b) evacuation resources, and (c) hospital-based resources (e.g., ED care, OR, etc.)?
- After initial triage, who reevaluates the casualties, and how often?
- Have all details of the triage plan been re-evaluated on an ongoing basis?
- Has an updated triage plan been communicated to all active rescuers, including victims and participating bystanders, as is appropriate?

disaster and the scope of casualties. Triage training is specifically discussed at the end of the chapter.

What Triage Classification Is Used? There are several issues to consider for planning a disaster response. First, will a multiple-level triage classification system be used? As noted in the previous section, there are precedents for responses to MCIs with over 100 casualties that consist of prehospital “scoop and run.” Then, rather than a rigid triage scheme outside of normative practice, casualties were in essence sorted into one of two categories using clinical judgment: OR or no OR^{14,16} These events were notable for a lack of clinically significant bottlenecks in field evacuation and hospital capacity, thus reducing the importance of triage.

In planning for a disaster, it hardly seems prudent to assume such ample evacuative and hospital-based resources would be available, but it does speak to the importance of mobilizing maximum resources. This is the impetus for a more formal triage scheme, such as a four- or five-level classification. In the common four-level system, such as the well-known civilian START system,²⁰ the categories are: (1) those who will get immediate priority (color-coded red), (2) those casualties who must wait (color-coded yellow), (3) those with the least severe injuries (often referred to as “walking well,” color-coded green), and (4) those casualties whose prognosis is so poor that there is no justification for spending limited resources on them (color-coded black). Military triage hierarchies have a similar four- or five-level structure, although the nomenclature is different. For instance, color code green is equivalent to NATO level T3. People responding to international disasters should be aware of all of the triage classifications used by the host country and by the other responding agencies. A slightly more complicated five-level system makes a distinction between patients who will not survive

(color-coded black) and those too gravely injured to receive limited resources (sometimes color-coded blue). But if enough resources become available, blue-coded casualties can then receive care. It has been argued that the option for an intermediate level such as blue may actually produce superior triage decision-making. Given a stark choice between red and black for gravely injured patients who are not yet dead, it might be emotionally difficult for responders to apply a black tag, even though resources would be wasted on the casualty with a very poor prognosis.

When a tiered triage system is to be used, the most complicated issue is selecting the formal criteria to use for assigning each acuity level. This is discussed in detail in the “Will a formal triage scoring system be used?” and “Are normative overtriage and undertriage rates acceptable?” sections. Most triage plans assume, and rightly so, that a casualty who can ambulate (i.e., the “walking wounded”) is truly low risk. In a review of nearly 30,000 routine civilian trauma casualties, Meredith²¹ find that the ability to follow commands (i.e., GCS motor = 6) upon arrival to an emergency department is an outstanding positive predictor of patient survival. Still, these casualties do require medical attention at some point; head or extremity hemorrhage, open fractures, or penetrating abdominal trauma are injuries that might be present in ambulating patients, which are manageable conditions that become dangerous if not treated within an appropriate timeframe. In Meredith’s study, the patients with GCS motor of 6 and outstanding prognoses received normative medical care, not indefinite neglect.

Will a Formal Triage Scoring System Be Used? A formal scoring system can help categorize casualties by objective criteria. Reliance on EMS subjective assessments of severity has been studied as an independent predictor of acuity in routine trauma patients (e.g., not disaster casualties). EMS judgment has been found to be better,²² equal,^{23,24} and worse^{25,26} than formal triage scoring. There is evidence that EMS judgment complements objective triage scoring.^{23,25,26} Also, these prehospital triage systems are tailored to traumatic pathology, not squeezing chest pain nor focal pain at McBurney’s point. The Glasgow Coma Scale (GCS), published in 1974, offered a historic means of stratifying prognosis after head injury.²⁷ Triage scores for individual trauma patients (see the Historical Perspective section) arose from the need to decide if individual trauma casualties should be transported to specialized trauma centers. The best known are Champion’s Trauma Score and Revised Trauma Score (RTS). The original Trauma Score used capillary refill and respiratory expansion, which were felt to be too unreliable. The RTS uses GCS, systolic blood pressure, and respiratory rate, and it yields a score between 0 and 12.^{8,28} An RTS of 12 predicts mortality of less than 1% (when given routine clinical care). Mortality of roughly 50% is predicted by an RTS of 5. In general, the use of physiologic criteria tends to be specific, but not as sensitive, for predicting critical injury. Other notable triage scores include the CRAMS and Triage Index, which have also shown suboptimal test characteristics.²⁹⁻³⁴ The advantage of a scoring system is that no particular physiologic state preordains a specific triage category; rather, scores

for “black” and “red” and “yellow” can be established in real time, based on the perceived balance of casualties and medical resources. Triage scoring offers a flexible, sophisticated approach to triage. However, in the chaos and uncertainty of a disaster—a high-acuity, low-probability event—“sophisticated” can become “complicated” and “flexible” can become “uncertain.” If formal triage scoring is to be of benefit, emergency responders must be extremely facile with its use if the benefits are to outweigh the costs. For triage of pediatric casualties, neurologic, cardiovascular, and respiratory triage criteria should be different from those for adults because of the differences in physiology and recuperative capabilities. This motivated the development of specialized pediatric triage criteria, including the pediatric trauma score^{35,36} and, more recently, the pediatric triage tape.³⁷ The former instrument did not prove superior to adult triage scoring systems,³⁸⁻⁴⁰ and the latter has not been extensively validated.

A far simpler alternative to triage scoring is a “cookie-cutter” triage algorithm such as the START system. This system, for example, assigns “red” based on a rigid set of criteria (if airway is compromised, if minute respiratory rate is over 30, if capillary refill is over 2 seconds, or if simple commands cannot be followed).²⁰ The Triage Sieve is another similar example of an inflexible assignment algorithm; it includes an upper and lower limit for “red” respiratory rate, as well as a fixed upper limit for heart rate (unlike START, it does not use capillary refill).⁴¹ The advantage of such rigid systems is the simplicity to teach and learn and the appropriateness for typical MCIs with dozens or hundreds of casualties. The disadvantage, the inflexibility, is discussed further in the Acceptable Overtriage and Undertriage Rate section.

What On-Site Documentation Will Be Used? The triage tag, a minimal document that can be attached to each casualty, might be the only practical method of communicating findings, interventions, and so on, as countless casualties are passed through a chain of emergency care. However, it has been argued that triage tags are impractical to use, and geographic triage (see later) can obviate the need for tags.³ In a disaster, hundreds or thousands of tags for each triage category must be immediately available to the responders, who need to be exceptionally familiar with the tags to use them properly under trying circumstances, and frenzied casualties may not take proper care of the tags. After an enormous disaster (thousands of casualties), tags might be especially challenging to use properly, although they could also be especially useful.

Consideration of the use of triage tags requires some research on the part of the customer, since there are over 120 triage label systems in use internationally.⁴¹ Hogan and Burstein⁴² suggested the following criteria for the optimal triage tag: (1) It must attach securely to each casualty’s body, (2) it must be easy to write on, (3) it must be weather-proof, and (4) it should permit the documentation of the patient’s name, gender, injuries, interventions, care-provider IDs, casualty triage score, and an easily visible overall triage category. It must also permit changes to be made, because triage is always dynamic. A detailed graduate thesis with a wealth of detail about this subject is presently posted on the Internet.⁴³

Who Will Be the Triage Officer(s)? There must be a major first-pass to establish which casualties can wait, which are top priority, which are expectant, etc. This can occur in the field and/or receiving hospital, but the designated triage officer needs a deep understanding of emergency medical treatments, what outcomes are likely for various casualties, and what resources are necessary for treatments. It may be advantageous to have a physician in this role. In Israel, the role is taken by the surgeon-in-charge, since the emergency care bottleneck following a suicide bombing MCI typically occurs in determining operative priority after rapid evacuation to a receiving hospital.¹⁶ Among multiple important traits, a triage officer needs the experience, disposition, and judgment to act as an able leader under incredible pressure.^{42,44}

Who Will Collect Vital Signs for the Triage Officer(s)? The measurement of vital signs should be delegated to assistants to the triage officer. Unfortunately, even in routine clinical conditions, vital sign measurements are confounded by human error and poor technique.^{45,46} Retraining improves the accuracy of vital signs⁴⁷; this is important, because during the chaos and stress of an MCI, an accurate set of vital signs determines the fate of an individual (e.g., placement in a triage category).

Physically, Where Will Casualties from Each Triage Category Be Cared for (and Who Will Staff Each Area)? Geographic triage means assigning casualties to different physical locations based on severity. Initially, casualties can be brought to a collection point. From there, the triage officer can determine the appropriate triage category (e.g., red, yellow, black, possibly blue), and then the casualty can be moved to a triage category-specific collection point for further on-site treatment and/or transportation. The walking wounded (green) are readily separated from more seriously injured casualties through good crowd communication and control; most of these casualties could be taken care of in an urgent care center, clinic, or private physician offices, and having some mechanism for directing these casualties away from larger medical centers may be valuable. It has been suggested that dead victims should be moved to an isolated location.⁴² Briggs⁴⁸ suggests the following are desirable characteristics for on-site triage and treatment locations: (1) proximity to the disaster site, (2) safety from hazards, (3) location upwind when contamination is an issue, (4) protection from climactic conditions, (5) easy visibility, and (6) convenient access for air and land evacuation. No ideal location may be available and the on-site collection point may of mixed utility. For example, during the Sept. 11 World Trade Center attack, only 6.8% of the victims who went to the hospital arrived by ambulance.⁴⁹ Quarantelli,⁵⁰ in a classic study of EMS in 29 U.S. disasters, noted that most casualties are not transported by a properly staffed ambulance, but by private cars, buses, taxis, and even on foot. Field triage and first aid stations are often bypassed, either because their location or existence is unknown, or because they are considered an “inferior” level of care compared with hospitals. Left to their own, minor or even critical casualties will evacuate themselves to a nearby hospital.^{3,42}

Following the Centennial Olympics bombing, ample EMS resources allowed rapid, complete evacuation of casualties, so on-site geographic triage was unnecessary.¹⁷ In small or large disasters, it may be preferable for the triage officers and litter-bearers to circulate and directly move casualties from the scene to appropriate treatment locations, eliminating any collection point. In extremely large disasters, several collection areas might be useful. Vayer³ cited a number of MCIs, including the Hyatt Regency skywalk collapse and the IBM shooting incident, in which a collection point for triage was useful. It is important to consider the manner and degree to which geographic separation will be enforced. The bigger the disaster, the more crowd control is an issue. For receiving hospitals, crowd control is a must and an unstructured influx of casualties should be anticipated, with most casualties ending up at the closest hospitals while those farther away will await casualties that never arrive. Following the Tokyo subway sarin attack, the St. Luke's emergency department was deluged with 500 patients in the first hour alone.⁵¹ At the scene, crowd control is a more complicated issue. Einav⁵² described how Jerusalem EMS evacuates casualties so rapidly that only minimal medical interventions are performed, and no crowd control at all is attempted. Crowd control requires emergency resources and may eliminate the assistance by untrained local citizens who constitute the majority of the response resources after disasters. Regarding crowd control on scene, Vayer³ suggested that "if patients are medically and emotionally stable and choose to leave, they should be allowed to do so."

What Overtriage and Undertriage Rates Are Acceptable, and What Level of Casualty Gets "Black-Tagged"? Investigations of trauma triage rules (the prehospital decision of whether or not a patient's severity warrants transport to a specialized trauma center) suggest that overtriage of 50% to 60% is necessary to achieve undertriage rates around 10%.^{4,25,26,31,42,53} It has also been noted that the four-tiered START triage algorithm leads to substantial overtriage of disaster casualties.^{9,42} This might be acceptable in a response to an MCI with a few hundred surviving casualties. Consider Table 43-1: After a hypothetical terrorist bombing with 100 to 200 surviving casualties, conventional triage practice might overtriage 50% of the intermediate "true yellow," increasing the number of total red. Would it be worth attempting a dramatic departure from normative triage to attempt to reduce the 10 or 20 "false reds"? Routine rates for trauma overtriage and undertriage may be ten-

able for incidents on this scale. It is worth examining other scenarios that suggest how overtriage and undertriage goals must be adapted to the scale of the disaster. An event with 1000 to 2000 surviving casualties would yield 100 to 200 "false-reds," in addition to the 200 to 400 "true-reds," if triage criteria were not appropriately adjusted (see Table 43-1). Such numbers of red critical casualties would likely overwhelm even a large urban area's facilities; therefore the rate of overtriage should be lowered even if that means increasing rates of undertriage (this is the classic sensitivity/specificity trade-off embodied by receiver-operator curves). There are in fact diverse options to how to define "black" casualties, who are considered so sick (e.g., pulselessness, apnea) that resources are wasted on them: An Israeli EMS protocol for MCIs is more specific, considering as dead those with amputated body parts who are not showing signs of movement, as well as those who are pulseless with dilated pupils.¹⁶ In published reports, there is mixed evidence that the overtriage of excessively sick casualties (e.g., the failure to apply a black tag to unsavable survivors) has been an issue. One retrospective analysis of seven separate terrorist bombings noted a correlation between high mortality rates for hospitalized casualties *with* critical injuries and the fraction of casualties hospitalized *without* critical injuries.⁵⁵ One explanation would be that overtriage of noncritical casualties cost the truly critical casualties the medical attention they required. On the other hand, the paper did not describe other characteristics of the casualties, such as the age of victims, the distribution of injury severity, and the incidence of head injury. These factors might suggest alternative explanations. Historically, resuscitation of moribund casualties following MCIs offers dismal outcomes^{14,56,57} and such heroic measures are generally discouraged. Failure to triage the unsavable as "black" (a form of overtriage) will produce "false reds" who will pointlessly be given precious medical resources (see Table 43-1). Indeed, in designing a response to an earthquake with many thousands of casualties, it has been suggested that casualties with a likelihood of survival less than 50% may need to be "black-tagged."⁵⁸ If so, a revised trauma score of 5 or less would be an appropriate criterion.⁸

Undertriage of the critically injured may be just as much of a problem, historically. Following the Oklahoma City terrorist bombing, 100% of the 72 casualties admitted to hospitals survived.¹⁴ Only 3 of the 167 fatalities were even transported from the scene, and those 3 were dead on arrival to the emergency department. Is it possible that

TABLE 43-1 SPECTRUM OF CASUALTIES FOR DIFFERENT SCALES OF DISASTERS (HYPOTHETICAL)

SURVIVING CASUALTIES	TRUE GREEN ~60%*	TRUE RED~20%*	TRUE YELLOW ~20%*	TOTAL RED TRUE RED + 50% OVERTRIAGE OF TRUE YELLOW†	EXPECTANT ~2%
100	60	20	20	30	NA
200	120	40	40	60	NA
1000	600	200	200	300	20
2000	1200	400	400	600	40

*Based on typical distributions of injury severity,⁵⁴ for illustrative purposes only.

†Based on typical rates of overtriage of less severely injured casualties, see text for details.

there had been savable casualties at the scene who never received needed care in time? It is important to not reflexively deprive serious casualties of the intensive care they may need when resources are available. Pepe and Kvetan² propose a scenario in which “there are 40 patients, 39 of whom are ‘walking wounded’ and one patient ... is in a state of cardiopulmonary arrest.” In such circumstances, standard resuscitation, or at least a “quick look” with a defibrillator, may be appropriate for patients who are moribund. Indeed, for both the Centennial Olympics bombing¹⁷ and the Israeli Sbarro bombing,⁵⁴ the balance between the spectrum of casualties and the available medical resources was sufficient that CPR and emergency department thoracotomies were attempted, respectively.

Ideally, triage criteria would be calibrated, using a severity score such as the RTS, to balance the scope of resources available with the scope of casualties. An ideal method would further consider not only mortality, but other issues such as functional outcomes or years-of-life saved. Realistically, however, it does not make sense to expect that the triage method can be tailored so carefully to a given disaster in real-time. Most disaster experiences suggest tremendous uncertainty exists about the extent of the casualties during the initial response^{10,54}; when extrications are necessary, the sickest patients are usually last to arrive.^{3,14} The “fog of war” complicates the initial responses to any disaster. At the same time, it seems prudent to prepare different triage plans for different scales of disaster (e.g., for dozens versus hundreds versus thousands of surviving casualties).

Assuming 10 Patients in 20 Minutes per Triage Officer,²⁰ Are There Enough Officers? Are There Enough Other Personnel to Keep up with the Triage Team (e.g., Litter Bearers, Care Providers). If not, Is the Triage Team too Big? In general, the litter bearers, triage officers, and other care providers will not always operate in perfect synchronicity, since there will be irregular hold-ups for various activities. Responders may need to briefly change roles during operations (i.e., a triage officer may hold pressure on a compressible site of hemorrhage for a few moments until someone else becomes available to take over). If any specific activity becomes truly rate-limiting (triage, stretcher transport, etc.), personnel should be reassigned to balance the response. Also, if extrication from the site is the rate-limiting step, triage can be moved to the site itself, so that extrication efforts themselves are triaged, with consideration given to both medical severity and the difficulty of extrication.

Are Resources Being Used Appropriately, Including (a) On-Site Medical Interventions, (b) Evacuation Resources, and (c) Hospital-Based Resources (e.g., Emergency Department Care, Operating Room)? This chapter on triage refers to “response resources” and “emergency care” in rather abstract terms. Detailed discussion gets into the excessively broad subject of trauma management and critical care. Yet, to understand and perform triage, one must understand the costs (in terms of time and materials) and benefits of the emergency care. For instance, putting pressure on an extremity hemorrhage or dressing an open chest wound should be high priority for any responder, since such simple measures can

save a life (assuming the casualty doesn’t have additional ominous injuries, such as a massive head injury). Other high-value on-site interventions can include splinting and, if critical care resources are permitting, airway support for decompensating patients. If the balance of responder resources to casualties is permitting, on-site intervention may even include some resuscitation (i.e., quick look with a defibrillator), although attempting such heroic interventions always runs the risk of using up precious responder resources. When neither evacuation nor hospital resources are bottlenecked, on-site interventions should be kept to a minimum. For those casualties evacuated by ambulance, consideration might be given to bypassing the closest hospitals. Also, casualties transporting themselves to the hospital could be advised which hospitals are not getting very many patients and therefore will have shorter waiting times. When evacuation from the scene is a bottleneck, common sense dictates that evacuation priority is for patients who would most benefit from timely hospital care. Suspected abdominal hemorrhage thus precedes compressible extremity hemorrhage, since the former requires an operating room while the latter can be treated initially in the field. A lucid but hypotensive patient with penetrating abdominal trauma should precede penetrating head injury with altered mental status, since the former has a better prognosis if prompt operative care is provided. At the receiving hospital, too, resources (operating room, blood cell transfusions, ventilators) should be triaged. One of the important and often overlooked issues in triage is redistributing the patient load. Receiving hospitals may reevaluate appropriate casualties to remote hospitals with available capacity. Some have argued for turning the closest hospital into a triage center and redistributing the casualties to other facilities from there. However, federal patient transfer regulations (EMTALA) do not make this easy.

After Casualties’ Initial Triage, Who Reevaluates the Patient, and How Often? After Each Reassessment, has the Triage Plan been Communicated to All Active Rescuers, Including Victims and Participating By-standers, as is Appropriate? A patient’s apparent clinical condition will evolve, as will the available resources. After an initial triage, a formal mechanism for ongoing reevaluation of casualties is necessary for all triage categories (with the possible exception of black). These clinical reevaluations can also establish treatment priorities within various triage groups, since, for instance, red casualties will have intracategory variation in terms of severity and the specific management they require. In some cases, conditions will worsen, and a yellow designation may become red (e.g., evolution of blast lung injury) or red designation may become black (e.g., hypovolemic arrest). In other circumstances, new resources may permit more aggressive care, and a blue or even black designation may be upgraded to red (discussed in the What Triage Classification Is Used? section). Even some of the walking wounded may have conditions that require timely intervention, in case an excellent prognosis is threatened. To effectively re-triage requires updated knowledge of the spectrum of casualties and the resources available; there should be a formal mechanism for such updates.

Focus: Training/Planning Specific Issues

This chapter described options for disaster triage. From a training perspective, the bottom line is this: more sophisticated systems may enable optimal triage, but one must fully commit to training and mastery of any system for it to be of value in the chaotic aftermath of a disaster. Therefore, a system such as START, with its straight-forward four levels and rigid criteria for each category, may be better than a fully improvisational approach that relies on clinical judgments, but not unless it is mastered in training. A five-level system may offer even better triage than a four-tiered system,⁴ but it is all the more complicated to learn and execute. Triage tags may offer better record-keeping and patient care, but they will prove simply burdensome if they are unfamiliar to the caregivers dealing with a major crisis. Finally, formal trauma scoring, such as Champion's RTS, might enable the most sophisticated triage, but not if the responders are struggling to properly compute the revised trauma score.

One suggestion for planning a triage response to a disaster is this: Select the most flexible methodology of which your training resources will permit mastery. Rehearsal is crucial, so that the principle of "normative practice" (see the opening paragraphs in this chapter) can be followed in an actual disaster. Authors have suggested the need for weekly practice for proper maintenance of disaster-response skills (e.g., "Triage Tuesday").^{3,42} Many triage systems rely on measured vital signs, but as noted, vital signs are often measured poorly even under normative clinical conditions; retraining such skills can be very useful. Formal triage scoring, such as the RTS, can also be used in *designing* simulations so that the survival rate of the hypothetical casualties can be computed and the performance of triage during the exercise can be evaluated objectively. Finally, there may be use to simple table-top simulations as an inexpensive, undemanding complement to full-scale rehearsals.

PITFALLS

- Ineffective triage after unexpected disasters has been the historical norm.
- Effective responses have used exceptional mobilization of prehospital and hospital resources, making triage easier.
- For planning, realize that disasters with dozens or hundreds of casualties have been the norm in developed countries.
- Don't assume that the triage plan for dozens or hundreds of casualties will be suitable for disasters of all scales and conditions.
- Don't assume that the majority of healthcare emergencies following large disasters will be traumatic in nature. Just because there is a disaster, people do not stop having coronary ischemia, asthma attacks, or miscarriages.
- Appreciate the enormous training requirements for any triage plan that deviates from normative health delivery practice.
- Appreciate trade-offs between utility and complex-

ity (four versus five triage levels, rigid "cookie-cutter" triage criteria versus flexible criteria using severity scores, triage tags versus geographic triage, etc.)

- Realize that vital sign measurement technique must be addressed in training.
- Select appropriate, safe locations on-scene and plan for crowd control.
- In real time: reevaluate, reassign, and relate updates to responders.

Patient Tracking Systems in Disasters

Charles Stewart

Recent acts of mass terrorism have called attention to the urgent need to improve response during mass-casualty incidents.¹ The risk of these mass-casualty incidents appears to be increasing as a result of population growth, industrialization (and concomitant use of high-energy chemicals and sources), and the threat of terrorism.²

One consistent challenge during the disaster response is communication and information management from the field to the care facilities. A critical interdependence exists: accurate information from the field about the incident, medical needs at the scene, numbers and types of patients and their injuries, and patients triaged and treated will affect the demand and use of resources such as ambulances, emergency departments, surgical suites and specialists, and intensive care units. Similarly, information on the availability of ambulances and hospital resources will alter the management and disposition of the victims at the scene.

Following the initial impact of the disaster, the casualties generated by this disaster must be determined. Relatives of patients will want to know where their loved ones are being treated, law enforcement officials may want to interview survivors and suspects, and public health officials will want summaries of patient conditions and dispositions. To respond effectively to inquiries about the missing, victim data *may* have to be collected not just from hospitals, but also from shelters, jails, and morgues. However, most disaster evacuees do not stay in public shelters, but rather seek refuge with family, friends, and neighbors. Therefore, they will need to be contacted via the mass media and encouraged to register via telephone hotlines or Web sites. Victim information should be collected at a central location and be made available via telephone hotlines or web sites distant from the impact area. (In very large disasters, the numbers of inquiries about the missing can exacerbate local telephone and cellular circuit congestion and shut them down momentarily.) Hospitals, concerned about Health Insurance Portability and Accountability Act (HIPAA) regulations and patient confidentiality, may be reluctant to provide patient information to the Red Cross or local authorities. HIPAA regulations do allow the release of information on patient names, locations, and general status for the purposes of notifying patients' next of kin. (See www.hhs.gov/ocr/hipaa)

Patient tracking is the art (and science) of determining which patient with which condition went to which destination (and where they are presently). This includes identification of the patient and identification of the patient's destination. Ideal practice would have the patient's medical records included with this tracking information.

HISTORICAL PERSPECTIVE

If the disaster happens in an isolated area, such as a recent complex multi-vehicle accident along I-80 in Wyoming, tracking of patients is relatively easy; most (if not all) casualties will be taken to one or two facilities.³ The major casualty tracking problem generated during this disaster was identification of victims who were burned beyond recognition. In most disasters, casualties may have multiple potential destinations.

Complicating the patient-destination match is the large number of patients who will take available transportation to a medical facility without involving EMS workers. For example, during the response to the Sept. 11 World Trade Center attack, only 6.8% were transported by ambulance.⁴ In addition, emergency response units from surrounding jurisdictions will often self-dispatch to the disaster.^{5,6} Accordingly, they may not be aware of existing local victim tracking system(s). Further complications include air evacuation to remote destinations, transfers to higher levels of care for patients with more complex conditions, and switch of destination during EMS transport.

CURRENT PRACTICE

There are two general types of tracking systems in current use: (1) paper tags, cards, and charts and (2) bar codes and Wi-Fi networks. A third type is currently in development.

Paper Tags, Cards, and Charts

Although separate from triage, the tracking process starts with triage. As patients are categorized by the

triage officer and assistant triage officers, they are tagged with a visible indicator of their priority (triage tags) or grouped with similar types of patients in a geographic area (geographic triage). Tracking starts with the recording of these patients (and as much data as time and condition permits) as they enter the medical care system.

When a triage or medical documentation tag is applied to the patient, the preassigned number on the tag is the patient's first identification in the system. In some systems, this tag may be the only reported identification and documentation of medical care of the patient until the patient is taken to the hospital.

The triage officer can rapidly prepare a patient tracking list containing the patient's identification number, sex, apparent age, triage condition, destination, and the time the patient left the scene. The receiving hospital prepares a similar list with identification number, sex, apparent age, triage condition, disposition, and time of disposition (Fig. 44-1).

Several commercially available tag systems can be purchased (Fig. 44-2). These include the METTAG and the Multi-Tag. These tags are preprinted with a unique number to facilitate patient tracking during an incident. Each contains a section for patient information and a section with tear-off strips to categorize the patient's condition.

These tags are advocated by multiple incident training programs such as the Major Incident Medical Management and Support training program.^{7,8} In these systems, either tags or a substitute such as pieces of colored aluminum, colored chemical light sticks, or surveyor's tape in multiple colors (red, green, yellow, black, or white) are used to tag each patient.^{9,10}

Other examples of medical documentation cards designed to travel with the patient include the NATO military "casualty cards" and the International Committee of the Red Cross casualty card.¹¹ Documentation cards that are attached to the patient in some form are more

likely to remain with that patient and document recent medical interventions to the receiving hospital.

There are several disadvantages to the use of paper tags and cards for patient tracking purposes.

- Application of tags takes time. There is only a single accident where triage tags have been described as being of benefit and this was limited to 22 live casualties.¹² Indeed, multiple casualties have been managed without triage tags and significant time was thought to have been saved in the Sioux City, Iowa DC-10 plane crash.¹³ (The alternative to triage tags was a geographical system of triage and sorting.)
- Triage tags are not weather resistant and may be destroyed or mutilated easily.¹⁴ Water can smudge and render illegible data on triage tags.
- Triage tags provide no advance information to the destination. (The information provided is also unavailable to other sites.)
- When patient information such as vital signs, condition, or even destination changes, it may be difficult to change the card/tag. Tear-off triage tags allow only unidirectional changes in the patient's condition.
- Tear-off triage tags may be changed easily by patients or family members in an effort to upgrade the triage classification and expedite medical care or evacuation.
- There is little limited paper "real-estate" space for continuation of vital signs and additional information. On the way to the hospital, the EMS provider can often obtain quite a bit of additional information, such as co-morbid factors like diabetes and heart disease, allergies, and current medications. The usual tag does not provide space for this information to the treating physician or medical provider.
- Triage tags are often discarded, even though they should be part of the medical record. They are

- often an awkward shape to put into the medical record and may not be recognized by the medical records clerks as part of the medical record.
- There are multiple tag and card formats available and these may be used in the same disaster by different teams. These may generate identical patient numbers for different patients as well as create confusion for medical providers receiving patients with different charting systems.
- When a destination is overwhelmed and the ambulance is diverted to a different destination, the paper triage tag does not reflect a new destination back to the triage officer.

- One of the factors that complicates the use of tracking systems (e.g., triage tags) is the tendency in disasters to abandon paperwork in favor of treating patients.¹⁵
- In some disasters, triage tags have not been available where needed.¹⁶

Triage tags do have significant advantages:

- They are cheap and simple to use.
- They are widely used, so many prehospital providers are familiar with their use and layout.
- They require little financial outlay for the disaster response team prior to the accident.

Bar Codes and Wi-Fi Networks

Recent advances in commercial package tracking as used by Fed Ex and UPS allow customers to find the shipping status and location of bar-coded packages and envelopes online. Extension of this technology to triage tracking remedies most of the faults of the paper system and allows the hospital, EMS dispatcher, triage officer, and other appropriate parties to track the human package from triage site to final destination. Alternative schemes with Palm collection devices to supplement basic triage tag data collection have added additional medical information and linked this to the triage tag and the medical record (Fig. 44-3).

By scanning a unique patient wristband at any location (disaster site, site treatment center, emergency department, and hospital ward, operating suite, or ICU), the system can track and provide the last known location of patients.¹⁷⁻²⁴ These systems have been tested in simulated disaster drills in the United States and Europe with good efficacy.

The addition of a Wi-Fi network collection point and compatible bar-code readers that upload to the network will allow real-time tracking, dispatch, and diversion updates to all participating hospitals and agencies. This gives any participating agency the ability to direct family members to the last known location of the patient.

Similar systems using a radio-frequency identification chip (RFID) can allow remote query of the triage tag or band.^{25,26} Marathon runners at large races are tracked during the race with similar technology, which can provide an accurate location of each runner during the race.

Bar-coded tags with Wi-Fi network do have some significant disadvantages, however.

- The technology requires a Wi-Fi network infrastructure to be set up at the disaster. This requires a substantial hardware and software outlay for all participating agencies and hospitals.
- The overall security of Wi-Fi networks is open to much question. Both modification of data and com-

FIGURE 44-3. Bar code reader used in St. Louis County bar code tracking system. (Reproduced from Hamilton J. Automated MCI patient tracking. *JEMS* 2003;28(4):52-56, with permission.)

promise of patient medical data can occur with Wi-Fi networks.

- The system may be unavailable if any electromagnetic jamming occurs and will be destroyed by any EMP effect, which is significant in the case of a nuclear weapon explosion.
- Each bar-code system represents a proprietary software system that may be incompatible with another similar system. This may have significance in adjoining city/county/state governments and some mutual response agreements.
- Bar-code systems require the presence of providers with scanning devices to obtain the tracking data. Keyboard entry of data can occur, but it is much slower and requires a computer with attendant power supply.

Use of barcode readers and networked computers has significant advantages to all parties, including the patient:

- Information about prospective patients is readily available to the receiving hospital. (Information about final destination is available to the dispatch officer for further transportation planning.)
- Information about patients at one facility is readily available to other participating hospitals and agencies.
- Information entered travels with a casualty and can be cross-referenced to medical history, when available. Allergies, medications, and co-morbid factors can be entered by participating sites at any point in the evacuation process. This information can follow the casualty through all levels of medical treatment and be concisely printed for the patient's final chart.
- Information is not limited to a small amount of paper "real estate." This information can even include pictures of the patient and identifying personal effects.
- Entry of initial data and identification of patients in a selected area are both rapid as the barcode is scanned with a reader.

THE FUTURE

The next stage in patient tracking is a wireless communication network to capture and display real-time casualty data, including continuous monitoring of vital signs. The U.S. Navy is investigating the use of a wearable plastic tag with an imbedded electronic chip that stores individual medical data, a palm-sized scanner that electronically reads and writes to the chip, and a central server that collects the database.²⁷ These smart-card "dog tags" allow data to be carried with the patient, rather than as a network. Use of small automated patient monitoring devices such as the Mobile Medical Monitor (M3) can provide automated data transmission of vital signs, linked to the patient's RFID.²⁸

Addition of global positioning data to the electronic tracking record will assist researchers in determining the

spot where a specific patient was found during the disaster for later incident reconstruction.

PITFALLS

- When there isn't a means of identification of patients/casualties with a unique identification number, tracking systems either lose all possible privacy and security or become quite difficult.
 - Surveyor's tape, light sticks, and aluminum tags do not allow the triage officer a ready system of counting patient numbers nor allow for numbered patient tracking. Another mechanism will be needed to provide this information.
 - Insufficient tracking tags or supplies for the mass casualty. This occurred during the early phases of both the Tokyo sarin attack and the Sept. 11 World Trade Center attack.
- Multiple entry points exist for casualties into the system. As was apparent in the Tokyo sarin attack, casualties often don't wait for a triage officer and ambulance before they seek medical care. The robust tracking system must be able to account for these patients as they progress through the system.
- Multiple triage tag designs may be used in the same incident, resulting in confusion for providers at all levels.^{29,30} This can occur when different agencies respond to the disaster and bring their own tags.
- Numbering systems or tag numbers may be duplicated. This can also occur when different agencies respond to the disaster and bring non-unique numbered tags to the disaster. This will totally confuse efforts at tracking patients.
- Failure to update the tracking model to reflect a changed destination can occur, which happens when ambulances are diverted from one facility to another. When this occurs, finding a patient can become quite difficult if multiple hospitals/receiving facilities are involved in the disaster.
- Inability to gracefully degrade or back-up an electronic system can occur. Battery life for electronic devices is limited. When power supplies and batteries run out, electronic systems will fail. Tracking officers should have a current paper back-up system readily available and should have hard-copy printouts of the current patient load prepared at set intervals. When power supplies fail, these hard-copy editions can gracefully assume the load without complete degradation of the tracking system.
- Given the difficulties ensuring that victim destinations are recorded during transport to hospitals, it is likely in many cases that these data will have to be collected *retrospectively* after transport has occurred.
- Several systems discussed in this chapter use electronic communications on radio frequencies that are easily jammed or use the Internet for communication. Since communications in a disaster is often a casualty of the disaster, the wise tracking officer must plan for this contingency and have a simpler back-up system available.

Tactical EMS

Jeffery C. Metzger and David E. Marcozzi

The earliest form of our current Emergency Medical Service (EMS) system emerged in the late 1700s from the need to transport and care for patients wounded in military operations. During the intervening 200 years, this early improvisation developed into the civilian EMS system that exists today. In recent years, with law enforcement focusing on covert and tactical operations, it has become evident that specialized medical support is necessary both to decrease the rate of morbidity and mortality and to increase the success rate of missions undertaken.

Tactical Emergency Medical Support (TEMS) refers to medical support for law enforcement operations. It has been defined by the National Association of EMS Physicians (NAEMSP) as “the spectrum of services necessary to establish and maintain the health, welfare, and safety of special operations law enforcement providers.”^{1,2} The term *emergency medical support* was intentionally chosen in place of *emergency medical services* to convey the wide range of functions beyond simple care for acute injuries during the operation. TEMS entails an overall contribution to mission success and the preservation of life and safety of all persons involved in a mission, including members of the tactical team, suspects, hostages, and civilian bystanders.

TEMS incorporates all levels of medical providers, including law enforcement officers with basic medical training; EMTs, paramedics, or physicians with basic law enforcement training; and dual-trained specialists with backgrounds in law enforcement and medical care. The inclusion of law enforcement duties by the TEMS providers should be limited as much as possible, regardless of the amount of training and experience the provider has. This allows the medical officers the ability to focus on medical duties, reduces the risk of role confusion, and decreases their risk of injury.

TEMS is not military medicine, although it does incorporate many of the rescue and treatment methods and the equipment used in modern military medicine. The resources available, types of wounds incurred, locations of operations, and mission objectives create for the TEMS provider a different environment than that of military medicine, requiring a unique approach to medical care.

HISTORICAL PERSPECTIVE

Since the earliest forms of organized warfare, armed forces have faced the challenge of transporting sick and injured combatants. The first methods were as simple as a strip of cloth attached to two poles, carried by other soldiers or livestock, such as camels and mules.³ The first recorded use of an ambulance was in 1487 during the Siege of Malaga. At this time, carts were used solely to transport wounded soldiers from the battlefield; no medical aid was rendered. Typically, transportation would not occur until after the battle was over, which meant leaving injured soldiers on the battlefield for hours or days. In the late 1700s, Napoleon Bonaparte appointed Dominique-Jean Larrey to develop a medical patient care system for the French army. Realizing that leaving the wounded soldiers on the field for days at a time increased suffering and mortality, Larrey developed a system in which trained medical personnel entered the battlefield to provide early access to medical care. One of Larrey’s important innovations was the design of the *ambulance volante*, or flying ambulance, a carriage staffed with medical personnel.^{3,4}

During the U.S. Civil War, Dr. Jonathan Letterman further refined the concept of the field ambulance based on the principles set forth by Larrey. Letterman designed special horse-drawn ambulance trains to transport patients from the battlefield to nearby hospitals. Also during the Civil War, Clara Barton recognized that giving medical aid to wounded soldiers on the battlefield as well as during transport improved their survival rate, and she made it a policy to “treat them where they lie.” Based on resulting improvements in wartime survival rate because of rapid access to medical care, the first civilian ambulance service in the United States was created in Cincinnati in 1865, instituting the public EMS system as we know it.³

A pivotal moment in the creation of TEMS occurred on August 1, 1966 at the University of Texas in Austin when one man, Charles Whitman, climbed the campus clock tower and proceeded to shoot and kill 15 people and wound 31 others.⁴ This incident, and the broader civil unrest of the times, prompted law enforcement agencies to create specialized teams to deal with high-risk situations.

As these teams proliferated and their roles became more defined, it became evident that close association with medical support staff with training in law enforcement tactics would enhance law enforcement missions.^{4,5}

By the 1980s, many specialized tactical teams were either training their own officers to render basic aid as designated medics or training medics in special tactics and law enforcement. In 1989 and 1990, two successive national conferences brought together experience and expertise of personnel from more than 40 tactical agencies across 10 states with representatives from EMS and emergency medicine with the goal of advancing tactical medicine.^{6,7} These conferences allowed for a collaborative effort toward defining goals and specifying minimum guidelines for medical support for tactical operations.

In 1990 the Casualty Care Research Center developed a national database to catalog the injuries sustained by law enforcement officers and civilians for the purpose of training officers and medical support personnel. In that same year, a collaborative effort between the Department of Defense, Department of the Interior, U.S. Park Police, Uniformed Services University, and Casualty Care Research Center led to the development of the Counter Narcotics & Terrorism Operational Medical Support (CONTOMS) course to provide the first comprehensive TEMS curriculum. Additional medical and professional support for TEMS began in 1993 when the California Chapter of the American College of Emergency Physicians organized the Subcommittee on Tactical Emergency Medicine to promote the availability of emergency physicians to tactical teams throughout California, with the eventual goal of expanding to the national level. Also during this year, the National Tactical Officers Association published a position paper supporting the idea of specialized medical support for tactical operations.⁸ In 1999, the National Association of EMS Physicians formed a task force to look at issues surrounding TEMS, and in 2001 it published another supportive position paper. More recently, the American College of Emergency Physicians added a Tactical

Emergency Medicine section to further promote the subspecialty and serve as a resource for physicians interested in TEMS. In addition, discussion boards, web sites, and organizations for every level of provider have been developed and are available.

CURRENT PRACTICE

A number of models of emergency medical support for tactical units are currently in use (Table 45-1).^{9,10} One common version is the “tactical 911” model, in which EMS is informed that an operation has been planned and is advised to have a unit on stand-by, either at the scene or nearby.¹¹ Another model involves designating an officer from the tactical unit as the medical officer. One model rapidly increasing in popularity is the “tactically trained medic,” with several variations available.

The tactical 911 model consumes the fewest resources and delivers trained medical personnel with a broad range of experience. Potential drawbacks include longer response times, the prospect of medical personnel that have little to no tactical training and are unable to enter the hot zone until the threat is secured, and the possibility of tying up a unit that otherwise could be serving the public. If the unit is pre-staged, the location is often chosen by the commanding officer and is likely to be far from where injuries are expected to occur. This scenario often means a site chosen without regard to the most strategic location for patient access or access to the best evacuation routes. Units are usually not called in for medical care until the scene has been secured.

Some tactical units train a law enforcement officer to provide medical care. This officer usually receives at least basic life support training and sometimes more advanced training such as paramedic or EMT-T training. Although this provides more expeditious access to medical care, the level of training and medical experience is often not as sophisticated as in other models. Another concern with this approach is role confusion (i.e., law enforcement officer versus medical provider). A med-

TABLE 45-1. TACTICAL MEDICAL SUPPORT OPTIONS

	PROS	CONS
Tactical 911	<ul style="list-style-type: none"> Most economical Consumes fewest resources No operational security concerns 	<ul style="list-style-type: none"> Variable levels of experience Unable to enter until threat is secured Takes unit out of service for public Staging location concerns No medical threat assessment Variable levels of training and experience
Law Enforcement Officer with Medical Training	<ul style="list-style-type: none"> Rapid access to medical care Access to medical care in the hot zone Familiarity with operational tactics Medic provides own security No operational security issues 	<ul style="list-style-type: none"> Possibility of role confusion Less familiarity with local medical resources
Tactically Trained Medic	<ul style="list-style-type: none"> Rapid access to care Access to medical care in the hot zone More experienced medical support Familiarity with operational tactics Medical threat assessment 	<ul style="list-style-type: none"> Consumes more resources Potentially not a sworn officer (weapon and arrest concerns) Operational security issues

ical officer performing law enforcement duties has an increased risk of direct injury during a mission, potentially jeopardizing medical care for the rest of the team.

A tactically trained medic is a medical provider such as a physician or EMT/paramedic who has received some training in operational tactics and trains directly with the unit.^{5,9,11} This allows the medic to operate as an integrated member of the tactical team, with an awareness of the unit's objectives and tactics. It is also important to make clear that the medic's role is primarily medical support and does not include law enforcement duties. The disadvantages associated with this method include liability issues and an increased concern for operational security, especially if the medic is not a sworn officer. This option is also more costly in terms of physical resources and personnel. Variations on this system include on-scene physician medical direction and varying levels of direct medical support in the hot zone. In addition, the medical support provided may be individual (from a single or small group of physicians and EMTs) or agency to agency (integration with the entire EMS system, hospital system, military bases, etc.).

The goal of a medical provider on a tactical team is to keep the team operating at peak performance and to increase the probability of mission success. This includes monitoring the general health of the officers; preplanning operations; monitoring safety measures; and providing medical care during training exercises, the mission, and afterward.

The medical support provided to tactical teams begins well before the start of an operation. Some of the preventive medicine administered by a medical officer may include ensuring that all members are physically capable of performing their duties, checking that necessary vaccinations are up to date, and confirming that thorough medical and psychological assessments have been completed.¹ Depending on the level of the provider, they can either perform these assessments themselves or refer the officers to their primary physicians. Duties may also include training officers in basic first-aid skills.

Training activities account for 24% of all missions that produce casualties.¹² Fortunately, these tend to be less severe than injuries sustained during operations. Medical providers are responsible for the care of these injuries as well as the prevention of injury and illness during training missions, including heat stroke, hypothermia, and hazardous chemical exposure. It is important to plan for necessities such as hydration and nutrition, especially during prolonged training exercises.

Operation preplanning is a crucial duty that greatly affects the safety of the officers and the success of the mission. This involves conducting a complete Medical Threat Assessment (MTA) and examining environmental factors such as weather, terrain, flora and fauna, and potential weapons and hazardous materials, such as those found in drug-manufacturing labs.¹³⁻¹⁵ At this point, ailments such as frostbite, heat illness, and dehydration, which may impair the success of the operation, can be foreseen and prevented. The TEMS provider may also play a role in equipment selection based on factors such as duration of the mission, environmental conditions, and

potential presence of hazardous chemicals.¹⁶ During preplanning, it is also important to plan evacuation routes and rendezvous points, anticipate the most appropriate definitive care sites, and calculate the optimal number of ambulances to have on standby.¹⁷ When considering scenarios in which air-evacuation may become necessary, determinations must be made regarding available aircraft, the coordinates of proposed landing zones, and nearby trauma centers with landing zones. Training officers in basic first-aid may also be beneficial. Some agencies issue all members a basic first-aid kit that includes bandages and tourniquets, which may prevent life-threatening exsanguination. Officers must be trained in the use of these devices on themselves and on other team members. Communication methods must be outlined, especially in cases involving potential periods of radio silence. The TEMS providers must also serve as advisors to the tactical commander, which means that recommendations should be offered but the tactical commander will make the final decisions regarding the medical logistics of an operation.

The team's medical equipment should be tailored to its specific needs, depending on factors such as team size, operational environment, mission objectives, and the training of the medical personnel. Factors such as noise and light discipline must also be considered, since bright lights or loud equipment can jeopardize a covert operation. Plans for managing an airway or placing an IV in low- or no-light situations must be considered prior to mission deployment. Portability is another important factor in equipment selection. For example, an extended operation with little opportunity for replenishment of supplies would likely require different equipment than one dealing with a barricaded suspect in a rural area. In any case, a basic kit would include bandaging supplies, gloves, tourniquets, airway supplies (possibly including surgical airway adjuncts), splints, IV kits, fluids, and medications. Those serving with K9 units will also want to keep a kit specifically for their dogs, including special airway equipment, bandages, a muzzle, and gloves.¹⁸ Extended operations will probably require supplies such as food, water, personal medications, and shelter, depending on the environment. Other potentially important elements include planning a rotation of personnel to allow for rest as well as determining the availability of other outside resources that may help the team maintain operational efficiency.

Medical care during the operation is divided into three stages: care under fire, tactical field care, and combat casualty evacuation care. These can also be thought of as care in the hot zone, warm zone, and cold zone, respectively. Traditional EMS teaching begins with scene safety. TEMS also incorporates scene safety, but with a slightly different emphasis. TEMS providers learn how to operate safely in a dangerous environment. Although the environment in which a TEMS provider operates is not always "safe," certain precautions can be taken to minimize risk. A major principle in TEMS is to provide only the necessary care while still in the hot zone before moving to the warm zone, and then to the cold zone. Determining the amount of care needed in the hot zone is often done with remote assessment methodology.

The patient is assessed without direct physical contact, such as the use of binoculars or some other communication system. This allows the medical team to determine the best approach to the patient and to plan strategies for intervention and evacuation before entering the hot zone. The best method of evacuation is self-extraction. When this is not feasible, the team must approach the patient and perform a rapid extraction (Fig. 45-1).

The amount of care provided prior to moving the patient depends on the severity of the injury, the degree of threat, and the transit risk (Fig. 45-2). The transit risk is comprised of three components. The first is the duration of transit. If the transit time will only be a few seconds, most treatments can be delayed until the patient has been moved to a more secure area. The second component is the route of travel. If the evacuation route crosses through the hot zone, it may be safer to stay in one place and begin providing care. The third component of transit risk is the ability to deliver care during transit. This becomes more of an issue the longer the transit time. If care will not be performed during transit, it may be beneficial to perform more care prior to transport to stabilize the patient. As a general rule, only the most critical interventions should be performed in the hot zone. Once in the warm zone, a rapid primary survey may be conducted to identify any immediately life-threatening injuries.¹⁹ This survey would include c-spine precautions, hemorrhage control, airway management, cardiopulmonary resuscitation, initiation of fluid resuscitation, and possibly administration of emergency medications such as analgesics. Consideration may also be given to splinting fractures and dressing wounds depending on the threat level. Attention must then be turned to moving the patient to the cold zone and finally to an appropriate definitive care site. Often there is no strict delineation between hot, warm, and cold zones. In a dynamic environment, such as that of a tactical operation, continuous reassessment of the risk-benefit ratio between medical treatment and extraction must be undertaken.²⁰

FIGURE 45-1. Medic team advancing on a vehicle. A medic trained in operational tactics can provide medical support in a hostile environment.

Care for the team may also involve caring for injured K9 officers.¹⁸ Treatments such as bandaging may help prolong the life of the dog until it can get definitive medical care at a veterinary hospital. Other treatments such as intubation, thoracostomy tubes, and CPR may also be useful, but this may expend valuable resources. A dog with trauma leading to cardiac and/or respiratory arrest is unlikely to survive, even with aggressive field care.

Medical aid for suspects must be performed with caution. They must be searched and any weapons found on their person must be safely disarmed and secured. It is also critical to keep in mind contingencies such as booby traps or other suspects hiding nearby. The most commonly reported type of injury sustained by suspects is gunshot wounds, followed by contusions and abrasions. Other possible types of suspect injuries include blunt injuries from less-lethal weapons such as bean bags and rubber pellets, flash-bangs, as well as the effects of chemical munitions. Flash-bangs have been reported to start fires and cause severe injuries, and even death, to suspects. Lacerations, sprains, and strains are also common injuries seen during the course of an operation.¹²

It may become necessary to treat civilian bystanders or hostages. Injury patterns for civilian bystanders are similar to those for suspects, with ballistic wounds being the most common injury.¹² Syncope from emotional stress may also be seen, but causes such as hypoglycemia or other preexisting medical conditions must be considered. Hostage care may be necessary and could include anything from blunt and penetrating trauma to psychological trauma or injury caused by the rescuing team as seen in Russia in October 2002. During this raid, a sedative gas was used to subdue the captors, but inadvertently killed over 100 hostages and hospitalized hundreds more.

The preservation of forensic evidence is of great importance during tactical operations.²¹ Evidence may play a critical role in subsequent legal proceedings and

FIGURE 45-2. Simulated wounded officer rescue. Tactical members rescue a wounded officer during a training exercise.

so must be handled properly to avoid altering crucial information or making it inadmissible in court. TEMS providers must have knowledge of what items constitute evidence and how to simultaneously perform their duties and secure evidence without disturbing it. Some examples include how to avoid bullet holes when cutting off clothing and how to handle weapons to avoid disturbing fingerprints.

Barricaded suspects and injured hostages present a unique challenge to the TEMS provider.²² “Medicine across the barricade” involves communicating with barricaded suspects or hostages to determine what injuries have occurred, the severity of the injuries, and what treatments can be applied. This is the subject of more detailed discussion in another chapter.

After the conclusion of an operation, the TEMS provider may be needed to clear the suspect for incarceration.²³ Providing a screening examination and treatment on-scene may prevent the suspect from requiring transport to an emergency department and the associated risks involved. The purpose of the screening examination is not to identify all medical problems, but to identify any life-threatening emergency conditions likely to require treatment. Although acute trauma certainly needs to be evaluated, other conditions such as bronchospasm from CS (tear gas) exposure and chest pain need to be assessed and treated. For serious injuries, transport may be required. The TEMS provider must have intimate knowledge of local regulations and policies for clearing a suspect in the field and must also be aware of the medical facilities available at the detention facility. If there are ever any questions, the provider should always err on the side of patient safety.²³

PITFALLS

Several issues surround the provision of medical support in hostile environments. One issue is the law enforcement status of the medical provider. TEMS providers may have the need for self protection and are sometimes armed during an operation. There are many legal and statutory implications involved with carrying and using a firearm in a tactical situation.²⁴ A provider may be open to civil liability should a weapon discharge and injure or kill a suspect or bystander during an operation. Further, the provider may not have recourse to the same protections as a sworn law enforcement officer. This may be resolved by having the TEMS provider become a reserve officer or deputy sheriff’s officer, or, more commonly, by having them remain unarmed but with an escort.

A similar issue involves the power of arrest and whether or not a TEMS provider can detain a suspect. These issues must be addressed on a team-by-team basis prior to initiating an operation.

Medical liability is another issue that surrounds TEMS.²⁴ Although full-time municipal medics may be covered under their agency’s policy, provided they follow established protocols, this must be confirmed in writing and they must still act in accordance with the

protocols of their department. All of this should occur under the medical direction of a physician. Physicians who participate in operations should protect themselves with liability insurance, which may or may not be included in their hospital policy. Insurance status and the details of coverage should be documented in writing prior to providing any care in this environment.

Infectious Disease in a Disaster Zone

Richard A. Tempel and David E. Marcozzi

Recent literature and media have raised the possibility of infectious diseases being used as weapons of mass destruction. Although bioterrorism certainly merits discussion, such as the anthrax incident of October 2001, there have been very few documented cases of such occurrences. This chapter focuses on postdisaster infection. The lack of clean drinking water, proper waste disposal, and the inability to receive prompt medical care all contribute to postdisaster morbidity and mortality. The worst of these scenarios tend to play out in Third-World countries, where densely populated regions are already barely sustaining their people. Programs such as the International Red Cross and Doctors Without Borders often place physicians in these impoverished regions. Identifying, controlling, and treating an epidemic in the setting of a natural or manmade disaster has challenged the knowledge and ingenuity of many physicians and will continue to do so in the future. The goal of this chapter is to provide a framework to assist physicians in the diagnosis and control of infectious disease in a disaster area and to explain where additional resources can be found.

The term *disaster zone* can be applied to a multitude of situations. Some examples of natural and manmade disasters include war, overcrowded refugee camps, industrial accidents, and bioterrorism. With increasing globalization and millions of international travelers and goods, we must also be aware that the victims of a disaster may turn up in emergency departments hundreds of miles from their original site.

The World Health Organization has defined a disaster as *a sudden ecological phenomenon of a sufficient magnitude to require external assistance*.¹ There are no specifics given pertaining to damages or fatalities. This is due to the fact that certain countries have disaster management plans established and may be able to contain an epidemic that may run rampant elsewhere in the world. The capability of a health system to tackle such situations can be defined by its *vulnerability*, which reflects the level of exposure to risk, shock, and stress.² A system may be more vulnerable due to poverty, gender, age, ethnicity, comorbid conditions such as HIV/AIDS, or religious identity. Exposure to warfare, destruction of property, and direct attempts to undermine care to the afflicted may also make a system less functional. The ability to handle

such factors may be referred to as *resilience*, or the ability to recover from adversity.³ Resilience can be increased, and vulnerability lessened, with proper planning and well-designed external support.

Recent estimates suggest that 65% of all infectious disease epidemics occur in countries deemed unstable.⁴ Forums established by the World Health Organization have noted that only 10% of global spending on health research is devoted to health conditions accounting for 90% of the global disease burden (the 10/90 gap), and that by 2020 the contribution of war and disasters to the global disease burden should increase from 12th to 8th.⁵ These numbers are troubling, especially when considering the rankings are based only on immediate morbidity and mortality, and not the long-term, indirect effects of disasters. The upheaval of health systems, access to quality food and sanitation, and economic decline undoubtedly heavily contribute to the total number of deaths due to infection and malnutrition.

HISTORICAL PERSPECTIVE

Historical literature abounds with examples of both war and natural disasters resulting in widespread infection and mortality, directly influencing the direction of human civilization. Although such catastrophes may have been simply part of life in the preindustrialized world, the implementation of sanitation and modern medicine provides the tools to prevent such epidemics today. Nevertheless, hundreds of thousands still die in Third-World countries annually due to the lack of preparation and inability to provide needed resources during and after major disasters.

In 31 BC, while preparing for his invasion of Italy, Marc Antony stationed his army estimated at 30,000 men on the hills above the marsh-bound city of Actium, Greece. Octavian, his rival, quickly encircled the city and camp on both land and sea, preventing supply wagons from entering, and even diverting the city's only supply of freshwater. Such tactics sent the soldiers and the people of Actium into the mosquito-infested swamps to find nourishment. Within 30 days, Antony had lost more than one-third of his army to disease and malnutrition, and Octavian soon became Augustus Caesar. Until the

end of the civil war, commanders expected to lose more soldiers from disease than from combat. The first military force to apply successfully all the technology of bacteriology, vector control, immunization, modern surgery, and echeloned care was the Japanese army in 1904-1905 during the Russo-Japanese War. It was the first army to suffer more deaths from enemy action than from disease.

In the sixth century of the Common Era, Hindu doctor Susrata suspected malaria epidemics to be related to seasonal mosquito infestations.⁶ The bark of the Peruvian quina-quina tree has been used for the treatment and prevention of malaria since at least the seventeenth century. However, it was not until 1897 that Sir Ronald Ross, using a microscope, deduced that the *Anopheles* mosquito was the vector for transmitting the *Plasmodium* parasite to its human host. This discovery, along with new methods to control the mosquito population, assisted in the expansion of the British Empire throughout the tropics.

Identifying the route of transmission for yellow fever has led to control measures in most developed countries. After the 1793 outbreak of yellow fever in Philadelphia, several physicians attributed its origin to be putrid coffee discharged by a shipping vessel.⁷ Construction of the Panama Canal started in 1880 by a French company and failed after 52,816 of its 86,800 men contracted yellow fever, and 5627 of these later died. In 1900, Maryland bacteriologists James Carrol and Jesse Lazear managed to prove an *Aedes* mosquito to be the vector for yellow fever, not by the microscope like Ross, but by inoculating themselves (Lazear later died of the infection). Directed by Major Walter Reed and General William Gorgas, this discovery led to the utter annihilation of mosquito populations (and forest) surrounding the canal. The Panama Canal opened in 1914, and the death rate surrounding the canal was half that of the United States at the time.⁶

In Angola, a 27-year civil war often applying "scorched-earth" strategies ended in a cease-fire on April 4, 2002. A large survey was conducted to evaluate mortality from June 2001 through August 2002 in parts of the region among displaced families.⁸ Estimates of crude mortality before the cease-fire reached 10 times that of other developing countries and up to 4 times greater among postwar, displaced populations, in part due to poorly funded United Nations assistance. Both before and after the cease-fire, malaria and other febrile illnesses remained the second leading cause of mortality in the study population. Also, a 23% mortality rate for infants was documented during this period. Examples such as this are evidence of the havoc that disaster can still inflict on humanity and the importance of the developed world to assist in times of need.

Children are often the most vulnerable immediately after a disaster. In developing regions, children are often fully dependent on their care-takers for both food and safety. Even those children who may appear well during a crisis period may fall prey to malnutrition and infection postdisaster, as evidenced by the survey in Bangladesh following its worst flood of the century in 1998.⁹ Such fragility requires serial evaluations of populations during and after a disaster so that those initially well may still have access to care if needed.

A recent epidemiologic study by the Japan Disaster Relief Medical Team in Mozambique noted the incidence of malaria increasing four to five times directly after a flood disaster in 2000.¹⁰ Water analyses noted an immediate deterioration in the quality of drinking water. This, combined with an increase in population density and food shortages, no doubt contributed to the 85% infectious disease rate among the patients receiving medical care. Notably, there was a lack of cholera or dysentery infection, which had previously been linked to similar disasters in the region.

In August 1999, the Kocaeli Province of Turkey was struck with a devastating earthquake.¹¹ An infectious disease surveillance system collected 1468 stool cultures over a 33-day period. The analysis revealed a multifocal, multiclonal increase in diarrheal disease, in particular, distinct *Shigella* serotypes and clones. The reasons why only this infectious agent showed such expansion is unknown, but it demonstrates the need for monitoring systems to better recognize infectious diseases after disasters and to initiate proper treatment.

In 1992, the Cerro Negro volcano erupted near the city of Leon, Nicaragua, and the health effects upon the 300,000 residents were assessed using routine data by the national epidemiologic surveillance system.¹² Healthcare visits for both respiratory and acute diarrheal illnesses increased up to six times when compared with pre-eruption data. Most of these visits were for children younger than 5 years old. Such results indicate the need to assess both air and water quality before and after an eruption and to provide data to better target at-risk persons. This type of data and response development would not be possible without Nicaragua's national epidemiologic surveillance system.

On October 26, 1998, Hurricane Mitch became, at that time, the Atlantic's fourth strongest hurricane ever and wreaked havoc in Central America, resulting in over 10,000 deaths by November 2. International and local medical teams responded, reviewing files from the region of Villanueva, Nicaragua, during a 3-month relief operation.¹³ The 30-day postdisaster incidence of acute diarrhea, respiratory tract infections, and malaria was estimated and compared with non-crisis data. The incidence of acute diarrhea doubled, and acute respiratory tract infection was four times more frequent. However, there appeared no significant changes in the incidence of malaria.

Although diseases such as malaria may become more frequent in disaster regions where resistance is already high, exposure to new diseases in more vulnerable populations is also of concern. In 1997 a severe, prolonged drought struck the Australasian region of Indonesia. During this time, more than 550 deaths due to "drought-related" disease occurred in the central highland district.¹⁴ Irian Jaya is home to both coastal lowland and shifting highland populations. The highland populations are known to have a low level of naturally acquired immunity to *Plasmodium falciparum*. On further study, microscopic evidence implicated malaria as the principal cause of death. A retrospective investigation revealed that increased standing water and food shortages resulted in a substantial demographic movement, thus exposing the highland population to malaria. In

October 1997, the rapid evaporation of stream beds and mass antimalarial drug distribution resulted in a precipitous decline in mortality. Examples such as these indicate the risks of population shifts associated with disasters and the need for continued health resource access.

CURRENT PRACTICE

The identification, treatment, and prevention of infectious disease has come a long way since Dr. Lazear's death from inoculating himself with yellow fever in 1900. Robert Koch identified *Bacillus anthracis* over 125 years ago, and Louis Pasteur developed an anthrax vaccine shortly thereafter.⁶ Nonetheless, October 2001 found the U.S. Postal Service in a crisis due to the spread of anthrax spores in the mail. Although it resulted in only 22 diagnosed cases (11 inhalation and 11 cutaneous) and only 5 deaths, the outbreak sent shockwaves through the American population. Such an event occurring in an industrialized country with a highly advanced medical system revealed our vulnerability to such incidents and sparked a revolution in infectious disease preparation, for both disaster and nondisaster areas.

The Centers for Disease Control and Prevention (CDC) serve as the lead agency in the United States for disease surveillance and have founded several global initiatives to battle infectious diseases.¹⁵ The CDC represents the lead federal agency for bioterrorism and epidemic response. Globalization has led to foreign diseases arriving on American soil, such as the 1999 outbreak of dengue fever in Texas, where 56 people were afflicted. The CDC has determined that it is far more effective to assist in the control and prevention of infectious disease outside of the country rather than to only attempt to prevent the importation. It would be impossible to examine all persons and goods entering the United States, and those who are asymptomatic would likely still be missed.

Several departments within the CDC work together to quickly assess an outbreak once identified and assistance is requested. The Health Alert Network was established to provide Internet and other forms of communication for local agencies to get advice and assistance from the CDC in an expedient fashion. A rapid response team is sent to investigate, confirm the presence of infectious disease, and assist in the control of the outbreak.¹⁶ The Laboratory Response Network provides laboratory testing, identifying the cause and determining effective treatment protocols. In 2001, the National Electronic Disease Surveillance System (NEDSS) was initiated for entering, updating, and electronically transmitting demographic disease data.¹⁷ This will allow rapid reporting of disease trends to control outbreaks and to monitor for bioterrorist attacks.

Although the location of the next infectious disease outbreak or bioterrorist attack cannot be predicted, a well-prepared disaster plan should be able to provide large quantities of medical supplies in an expedient fashion. The Strategic National Stockpile (SNS) program provides this resource for the entire country.¹⁸ It is a repository of antibiotics, antidotes, antitoxins, life sup-

port medications, and other medical/surgical supplies that may supplement and supply state and local health agencies in the event of an infectious disease outbreak. The SNS may be deployed once the affected state has requested assistance from the CDC. Initial deployment consists of "push packages," which are caches of pharmaceuticals, antidotes, and medical supplies designed to address a variety of agents and ready for delivery anywhere in the continental United States within 12 hours. Although not a first-response tool, the National Pharmaceutical Stockpile (NPS) will help augment state and local agency supplies. If additional resources are needed, follow-up vendor-managed inventory supplies can be provided within 24 to 36 hours and can be tailored to the specific needs of the state.

The CDC also works by invitation outside the United States. During a civil war and famine in southern Sudan, a hemorrhagic fever had affected 20,000 people and resulted in 2000 deaths.¹⁵ The CDC assisted the World Health Organization (WHO) in identifying the causative spirochete and implemented measures for disease control. In 2000, the CDC joined a WHO-led investigation of a tularemia outbreak among 500 to 1000 displaced persons returning to damaged homes and farms in rural Kosovo.¹⁵ It became clear that there had been an explosion in the rodent population due to unprotected stocks of food and crops, and the refugees returned home and ingested the contaminated food or water. This epidemic was halted by simple sanitation measures.

Several global health initiatives have recently been initiated by the CDC, including the following:

- Roll Back Malaria: Designed to reduce deaths from malaria by increasing access to prompt and effective treatment, as well as protective intermittent therapy for pregnant women, barrier prevention techniques, rapid response to outbreaks, and new products for prevention and treatment.
- Stop TB: Includes several objectives including the implementation of the directly observed therapy short-course strategy.
- International Partnership Against AIDS in Africa: A Joint United Nations Programme on HIV/AIDS-led effort assisted by the Leadership and Investment in Fighting an Epidemic initiative, providing support to countries hit heaviest by HIV/AIDS.
- Global Alliance for Vaccines and Immunization: Program to strengthen childhood immunization programs in foreign countries.

In addition to the CDC, the WHO provides immediate care anywhere in the world where disaster and infectious disease have overrun the local resources of a country. As an operational organization of the United Nations, the WHO acts as the directing and coordinating authority on all international health activity.¹⁹ On December 26, 2003, a devastating earthquake shook the city of Bam in Iran, killing as many as 30,000 people. With most hospital and health centers destroyed, and approximately 80% of all buildings damaged, local and neighboring health facilities were overwhelmed with the needs of the 100,000 residents of the Bam area. The WHO completed a rapid health assessment on

December 27 and immediately became involved in the provision of food, clothing, sanitation, and medical supplies.²⁰ Their surveillance systems have also documented all infectious disease and further morbidity and mortality in the area. Weekly assessments available to the public on the WHO Web site allow for identification of potential outbreaks and better allocation of resources to prevent further misery from befalling the people of Bam. Three weeks after the earthquake, there were no new outbreaks of disease and the incidence of diarrhea and other infectious diseases has remained at pre-disaster levels.

In 1859, during the War of Italian Unification, Henry Dunant witnessed the suffering of 9000 wounded troops in the small town of Solferino, Italy. This experience led him to initiate the groundwork for both the Red Cross and the Geneva Conventions. In 1863, the International Committee of the Red Cross (ICRC) was established. Comprised of both private and public funding, the mission of the ICRC is to "protect the lives and dignity of victims of war and internal violence and to provide them with assistance."²¹ National Red Cross societies exist in 178 countries, providing local care and international aid if requested by the ICRC. The concerns of the ICRC often overlap that of the WHO, providing additional support in regions of violent conflict.

In 1971, Doctors Without Borders, or Médecins Sans Frontières (MSF), was established to provide international emergency medical care.²² Volunteers are sent to the most remote and unstable parts of the world to provide emergency medical care to victims of both man-made and natural disasters. They can provide medical or surgical care, nutrition, sanitation, and local health training quickly and efficiently throughout the world, often working together with the United Nations and the WHO. MSF has been awarded the Nobel Peace Prize for its efforts in emergency medical care.

Local and regional agencies are still required, and essential, as the first responders to a disaster zone. Proper planning and practice have been shown to lead to less confusion and fewer deaths after catastrophic events. Both the NEDSS established by the CDC and the surveillance system in place in Nicaragua provide essential demographic information and the ability to locate disease outbreaks, quickly mobilizing resources for immediate care. The Demographic Surveillance System of the International Centre for Diarrheal Diseases Research, Bangladesh, was used to determine the effectiveness of flood-control embankments in disease prevention in children aged 0 to 4 years.²³ Crude child mortality was reduced by 29% in areas of embankment, but also of importance was the overall 40% reduction in all causes of childhood death due to increased health interventions.

In 1999 the city of Spokane, Washington, experienced a local scare involving anthrax. Deaconess Medical Center, in conjunction with the city, developed a program for obtaining information and antidotes for a variety of biologic agents. Within a year of the incident, a cooperative citywide response to a bioterrorist strike had been implemented. The roles of emergency personnel, hospital physicians, risk-management personnel, and law enforcement have been clearly delineated, and

Spokane's local agencies are now more prepared for such an event.²⁴

The importance of informing and mobilizing the public cannot be overemphasized. Television, radio, and the Internet can provide vital information from local, state, and federal agencies to large numbers of people in a short amount of time. A recent survey examining the public perception of information sources during a bioterrorist event noted the importance of both local and national spokespersons and periodic updates in maintaining public confidence and security.²⁵ Faced with a disaster, the local and neighboring populations often provide the most immediate life-saving resources, as evidenced most recently by the overwhelming response to the World Trade Center disaster of September 11, 2001. Blood donations tend to greatly increase during times of crisis, and a study evaluating the safety of blood donations after the 1989 San Francisco earthquake revealed these donations to be as safe as routine donations before the disaster.²⁶

The incidence of infectious disease in the disaster settings can be curtailed by implementing local surveillance systems to monitor for outbreaks and encouraging early vaccination as needed. Rapid disaster response strategies that provide survivors with immediate shelter, supplies, and clean drinking water have already contributed to fewer deaths and less suffering in developing countries.

Providing clean water and proper waste disposal are of utmost importance after a natural disaster. Large, displaced populations short on supplies often become fertile ground for diarrheal diseases. It is often difficult to supply remote areas with large tankers of clean water in the midst of violent conflict or natural disaster. Studies have shown simple water sanitation techniques such as heating, agitation, or exposure to sunlight may greatly decrease the incidence of these diseases.²⁷ A controlled field trial in 1996 showed a 26% decrease in diarrheal disease among Masai children in Kenya using solar radiation alone.²⁸

A developed country with proper disaster management strategies in place is likely to be the most resilient when faced with a disaster, both during and immediately after. When a flash flood occurred in the region of Nimes, France, in 1988, 45,000 people had their homes damaged or destroyed, yet only 3 severe injuries and 9 deaths were reported. No new infectious disease epidemics were noted afterward.²⁹ Results such as this are undoubtedly due to the immediate response of well-trained personnel and distribution of supplies to the victims of the disaster.

In conclusion, infectious diseases in disaster zones have often accounted for greater morbidity and mortality than the disaster itself. Diarrheal and respiratory diseases tend to be the primary culprits, targeting the infirm and the young. Developing countries are often more vulnerable to these afflictions due to the lack of available resources. Both in the United States and abroad, efforts are being made to control unnecessary postdisaster suffering. By installing effective surveillance systems to track infectious disease incidence, and rapid response personnel who are both well-trained and well-equipped, we can improve the resilience of a region. Yet until all human life is considered worth saving, and the 10/90 gap is cor-

rected, it will not be possible to reach this goal. Nevertheless, as evidenced most recently by the WHO response to the earthquake in Iran and the overwhelming response to the 2004 Tsunami in the Indian Ocean, steady progress is being made toward controlling disease in areas where this was once considered an impossibility.

PITFALLS

Although many local and international agencies are available to respond to disasters with strategies to quickly bring personnel and stockpiled supplies, limitations still exist. Remote locations in heavily forested or mountainous regions may lack roads or landing sites from which to deploy large-scale response services. Warring factions often prevent aid from reaching their rivals, or more frequently, the suffering civilians are caught in the cross fire. Some areas may be so dangerous that international agencies will not deploy relief workers, or they may be recalled for fear of injury or death, as seen recently with MSF withdrawal from the Darfur region of Sudan. Specific governments may even refuse help when offered due to political or personal motives.

The fall of the Soviet Union and unmonitored biologic weapons programs in unstable countries may provide terrorists with weapons ranging from anthrax to genetically engineered recombinant microbes. These weapons may be intentionally released anywhere in the world.

In 1975, the Biological and Toxin Weapons Convention was signed by 144 countries, yet it has been shown to be an inadequate control mechanism.³⁰ Most countries lack the laboratory safety requirements, necessary highly trained personnel, and ability to mass quarantine in the event of a microbial terrorist attack.³¹ Although the vaccination of United States emergency personnel to smallpox was deemed a success, it is yet to be determined whether there was an actual need or whether it will be effective should such a catastrophe occur.

Strategies are being devised worldwide, yet at this time few countries are prepared to handle a widespread attack with a contagious pathogen. This correlates to the rarity of these events in recent history because it is difficult to prepare for an event that has only been theorized.

Pharmaceuticals and Medical Equipment in Disasters

Nicki Pesik and Susan E. Gorman

Disasters can affect a community in many ways, ranging from the destruction of communication and transportation systems, to the loss of personal property, to overwhelming the capacity of medical and health systems. Most natural disasters create a predictable pattern of public health consequences.¹ Emergency health planners can use this knowledge to plan for the needs of a community in terms of resources such as medical and health supplies, communication equipment, and other materials. In addition to natural or technologic disasters, the threat of domestic and international terrorism involving weapons of mass destruction has become an increasing public health concern in the United States and abroad.² The medical supplies and equipment used to address events involving weapons of mass destruction often differ from those needed in response to a natural disaster.

Vulnerability assessments and hazard analyses are methods of identifying the hazards and vulnerabilities present and for determining their effect on a community. The vulnerability of a community results from factors that limit its ability to absorb and manage an emergency or disaster.³⁻⁴ Regardless of the disaster, vulnerability assessments should occur continuously throughout the event to determine the ever-changing needs and priorities of the community as the event evolves.^{4,5} Particularly in the case of deliberate acts of terrorism, epidemiologic and surveillance information is critical in helping to determine the current and predicted numbers of casualties and to provide emergency planners with critical information regarding the amounts and specific types of medical supplies or equipment required.⁶

Resources are required that most immediately address critical medical needs of the affected victims. Water, food, shelter, and equipment are needed next.¹ Effective resource management requires several basic actions: (1) determining specific resources and the amounts, (2) procuring the resources, (3) preparing an organized and secure area for storage with an inventory tracking system, (4) preparing to receive large amounts of unrequested medical assets, (5) identifying a means to transport and distribute resources where they are needed, (6) identifying locations for dispensing pharma-

ceuticals or other medical assets, and (7) developing the system for dispensing the medical assets.⁷

Equipment and supplies that are essential to the response capacity of a community can be generally categorized into several areas: direction and control, communications, mass care, and health and medical supplies. Equipment and supplies for health and medical care may be divided into two broad categories. The first category includes the drugs, medical equipment, and supplies that are necessary for direct patient care. This also should include provisions for maintaining primary care services in addition to the medical and health needs created by the disaster. Many patients will seek medical care for chronic conditions because their pharmacies and primary clinics have been destroyed or have become nonoperational.¹ Primary care medicines are often required.^{8,9} The second category includes the logistical and occupational health supplies used to support the emergency caregivers and facilities. Some examples include portable shelters, tents, portable water containers, patient stretchers, and personal protective equipment.

Initial steps should be taken during a vulnerability assessment to identify and inventory existing resources, equipment, and supplies that are essential to health and disaster management.¹⁰ Although the federal government may provide a variety of assistance, including medical assets and equipment, it is not expected that this assistance will arrive until 12 to 24 hours after a formal request.¹¹ International aid often does not arrive for 48 to 72 hours.^{1,7} International requests for field hospitals should consider the World Health Organization–Pan American Health Organization (WHO-PAHO) Guidelines for the use of foreign field hospitals. As demonstrated in Bam, Iran, in December 2003 following an earthquake, field hospitals should be operational within the first 24 hours to be useful and should remain on-site for a minimum of 15 days.^{12,13}

Determining the quantities of medical supplies and pharmaceuticals needed will depend on several factors, including (but not limited to) the specific threat or disaster, availability of medical assets within the community, extent of disruption of the medical and health systems, number of patients, clinical treatment or prophylaxis protocol, and time to the recovery phase of the disaster response.

Attempts have been made to quantify pharmaceutical stockpiling or evaluate preparedness of emergency departments for an event involving a chemical nerve agent. Resource needs have been estimated for 50 to 500 casualties exposed to chemical agents during one event.^{14,15}

HISTORICAL PERSPECTIVE

The Homeland Security Act of 2002 and Homeland Security Presidential Directive (HSPD)-5 required the creation of the National Response Plan (NRP), which will supersede the Federal Response Plan. The NRP outlines and describes the federal resources available to augment or support incident management. The NRP applies to incidents of national significance such as threats or acts of terrorism, major disasters as defined under the Robert T. Stafford Disaster Relief and Emergency Act, and catastrophic incidents defined as those events that result in extraordinary levels of mass casualties, damage, and disruption affecting the population or environment of a community. The NRP will contain a Catastrophic Incident Annex that establishes the coordinated strategy for delivery of applicable federal resources and capabilities that will address mass care, search and rescue, decontamination, medical support, and medical equipment.¹⁶

In 1998, the Centers for Disease Control and Prevention received funding under an Anti-Bioterrorism Initiative to develop the Strategic National Stockpile (SNS) program to assist states and communities in responding to public health emergencies, including those resulting from terrorist attacks and natural disasters.⁶ The SNS program ensures the availability of medicines, antidotes, medical supplies, vaccines, and medical equipment necessary for states and communities to counter the effects of biologic pathogens, chemical nerve agents, radiologic events, and explosive devices. The SNS program is designed to deliver medical assets to the site of a national emergency within 12 hours of a federal decision to deploy medical assets. Medical assets available within the SNS program include antibiotics, chemical nerve agent antidotes, intravenous fluids, intravenous administration supplies, bandages, burn ointments, analgesics, antiemetics, sedatives, antiviral medications, antitoxins, and vaccines.

A 12-hour response time for delivery of chemical nerve agent antidote is not optimal for the initial care of casualties. In addition, many hospitals carry only limited stocks of chemical nerve agent antidotes.¹⁴⁻¹⁷ These antidotes have variable shelf lives, and replacing them is costly and may impact a community's ability to respond. Therefore, the SNS program is currently executing a nationwide forward deployment of chemical nerve agent antidotes under its CHEMPACK project. Through this project, emergency medical services and hospitals will have access to chemical nerve agent antidotes for immediate use during an event.

CURRENT PRACTICE

There are multiple sources for clinical recommendations with regard to the treatment of casualties of events

involving biologic, chemical, or radiologic weapons.¹⁸⁻²² Recommendations regarding personal protective equipment have been hampered by limited regulatory guidance and lack of focused research on personal protective equipment for use in healthcare facilities. However, the current consensus appears to support the use of Level C personal protection (e.g., splash suits, gloves, boots, air-purifying respirators) in most healthcare settings.^{23,24} The public health consequences of disasters should also guide emergency planners in assessing the pharmaceutical and medical equipment needs of their communities.¹ Several medical equipment and supply lists exist and can provide examples from which emergency planners may select and begin developing an inventory that is appropriate for their populations and threat analysis.

An international resource is the WHO's *New Emergency Health Kit*.²⁵ This publication offers a standard list of essential emergency health supplies that are widely accepted internationally. Contents are calculated to meet the needs of 10,000 persons for 3 months. The kit inventory is divided into 10 identical units that would treat 1000 persons, so it is scalable to need. It is designed to meet the needs of a refugee camp and the priorities associated with austere conditions in developing nations.²⁵ In addition, the WHO has published and developed an essential drug list that identifies those pharmaceuticals that should be available at any given time in appropriate amounts and formulations. The WHO essential drug list has been adopted by numerous international agencies that supply pharmaceuticals within their healthcare programs and is being used to evaluate the appropriateness of drug donations.^{26,27}

The SNS program's formulary is directed at biologic, chemical, radiologic, and explosive weapons. Table 47-1 is an overview of the pharmaceuticals used against a variety of agents or events that are contained within the SNS program's formulary. Table 47-1 is not a comprehensive list, but rather, represents categories of medical supplies that can be used to respond to different threats.

A list of medical supplies for healthcare personnel responding to victims of earthquakes has been recommended by emergency medicine faculty at the University of California, Irvine, Medical Center. This list is intended for incorporation into medical backpacks and would be kept with specially trained medical personnel in the trunks of their cars at all times.²⁸

Centralized or decentralized stockpiles of medical supplies and equipment may be considered as an option for disaster preparedness. Certain biologic threat agents will require prophylaxis of persons responding to the event. Prepositioned stockpiles can reduce the time to prophylaxis for first responders and provide a sense of security for their welfare. Medical stockpiling may be one option for treatments that must be given within minutes to hours after an event and often much sooner than federal assistance can arrive. Communities with specific technologic risks, such as chemical storage depots or nuclear power plants, may consider the stockpiling of specific antidotes or treatments as part of their disaster plan.

Stockpiling medical assets is an expensive disaster response option.⁷ Costs are not only associated with the

TABLE 47-1 PHARMACEUTICALS AND MEDICAL EQUIPMENT IN THE SNS FORMULARY

GENERAL MEDICAL ASSETS	CATEGORY A AGENTS	CHEMICAL NERVE AGENTS	RADIOLOGIC EVENT	CONVENTIONAL WEAPONS
Emergency airway equipment	Ciprofloxacin	Mark 1 Kits	Prussian blue	Suture material
Analgesics	Doxycycline	Atropine	Ca DTPA	Laceration repair kits
Antiemetics	Gentamicin	Pralidoxime	Zn DTPA	Burn ointments
Sedatives	Amoxicillin	Diazepam	Potassium Iodide (KI)	Burn bandages
Intravenous fluids	Rifampin	Pediatric atropine	Cytokine	
Intravenous administration kits	Vaccines	autoinjectors		
Bandages	Antitoxin			
Emergency resuscitation medications				
Ventilators				

initial purchase of pharmaceuticals or equipment, but budgetary considerations must be in place to replace products as they near expiration. Equipment must be maintained and quality assurance provided. Equipment may also need to be replaced as newer models become available. There may be significant logistical costs associated with maintenance, storage, and transportation of the inventory.

Beyond the financial concerns of stockpiling medical supplies and assets, there are multiple logistical and clinical considerations for states, communities, or hospitals to consider. A major component of stockpiling medical assets is determining the storage locations. Pharmaceuticals should be stored in a secure and temperature-controlled environment. An inventory system should be incorporated into any stockpiling program that allows for up-to-date access on available products, notice of impending expiration of product, controlled access to restricted pharmaceuticals such as narcotics, and tracking of distributed products or assets. A centralized storage system of medical assets must be combined with an efficient and secure distribution system. Medical assets should be considered that have longer expiration dates and require no specialized storage needs or ancillary supplies.

Clinical considerations include assessing products for duplicity of use. Products that can be used to respond to multiple agents or events can reduce the number of pharmaceuticals purchased. For example, doxycycline has a Food and Drug Administration (FDA)-approved indication to treat multiple biologic agents including, anthrax, tularemia, and plague. Decisions regarding the formulations of products should consider special populations such as antibiotic suspensions for children or those persons who cannot swallow pills. Appropriate sizes of medical equipment for children should be considered.^{15,29} Planners should also recognize that the use of certain medical equipment, such as personal protective equipment, may pose a risk to their healthcare workers. Appropriate training for the use of all stockpiled equipment should be considered.²³ Medical personnel in charge of stockpiles used to address biologic, chemical, or radiologic agents will need to regularly review their formularies for inclusion of improved vaccines, newer treatment modalities, and changes to a drug's approval status by the FDA.

PITFALLS

Problems in disaster resource management can result from insufficient information or assessment of a community's health and other needs. There are countless examples of useless medical supplies and consumables sent to a disaster site, such as drugs labeled in a foreign language, expired drugs, or drugs not commonly used in a particular country.^{7,30-33} Most unsolicited medical supplies arrive unsorted, unlabeled, mislabeled, or not intended for emergency use. Time and effort must be expended to determine which resources are needed and which must be discarded. During the 1988 earthquake in Armenia, the donation of tons of pharmaceuticals and other medical supplies overwhelmed the local capacity to store and inventory the donations. At least 50% of medical assets donated to Bosnia and Herzegovina between 1992 and 1996 were considered inappropriate.^{32,34-35} Pharmaceutical donations sent to southern Sudan and Lithuania contained potentially dangerous drugs of which at least one, closantel, resulted in adverse side effects.^{36,37} The WHO has prepared general guidelines for pharmaceutical donations that include the selection of drugs, quality assurance and shelf life, packaging and labeling, and information and management of pharmaceuticals.^{27,33,36} Other examples include specialized external medical teams that arrive too late or are inappropriate for the response. These personnel then require food, shelter, and transportation.³⁸ Inappropriate and unrequested aid can cost a community money in the storage, handling, and destruction of medical assets. The cost of handling the drugs often exceeds the actual value of the pharmaceuticals themselves.^{33,35,39-40}

During international aid response, inappropriate, unneeded, or excess aid can arrive for a variety of reasons, including the belief that any type of international assistance is useful and the affected community is incapable of handling the response themselves.^{30,40} This may be the result of lack of communication between the donor and recipient, which leads to unnecessary donations.³³ Assigning personnel to be responsible for inventory control and assessing the overall response needs is often not done.³⁹ In an effort to provide nations with a supply management system, the WHO developed a system known as the Supply Management Project (SUMA).

The purpose of SUMA is to assist nations in categorizing and inventorying donations supplied during relief efforts.⁴⁰ Finally, unrequested and inappropriate donations have occurred because donors may want to receive tax deductions or avoid the costs associated with the destruction of medical supplies with short expiration dates, a practice that has been referred to as “drug dumping.”³⁵

SUMMARY

The types and amounts of medical equipment and pharmaceuticals required to respond to disasters will be determined by the disaster itself, the response capability of the community, and existing resources within the community. There is no specific list of pharmaceuticals or medical assets that apply to all communities or for all types of disasters. United States federal assistance is, in many cases, designed to augment the community and state response to disasters. It is therefore imperative that communities preidentify the medical resources available for a disaster response such as through the Metropolitan Medical Response System program, SNS program, Department of Veterans Affairs, and regional pharmaceutical caches that may be approved through Health Resource Services Administration grants. Preidentification of available assets will help to avoid duplication of efforts. Communities should closely coordinate the arrival of federal assistance with a distribution system that can efficiently transport critical medical assets where they are most needed. Pre-disaster preparations may include stockpiling of pharmaceuticals and equipment to respond to a variety of disasters. Although the financial implications of medical stockpiling should be addressed, there may be several reasons to consider stockpiling as an option in pre-disaster preparedness. Stockpiling or forward placement of pharmaceuticals may be considered when the timing of their administration requires that the product be given within minutes to hours to maximize their effectiveness, when limited supplies are generally available within a community, and when hazard assessments indicate a technologic risk to a community. Understanding the pharmaceuticals and medical equipment needed for a disaster should, at a minimum, include taking an inventory of community assets and considering the federal resources that may be requested.

chapter 48

Displaced Populations

John D. Cahill

Displaced populations have occurred throughout the history of mankind. A large population can be displaced by a multitude of disasters. These include, but are not limited to, natural disasters (e.g., floods, famine, earthquakes, hurricanes, monsoons, and volcanoes), persecution, conflict, and war. As seen in the Hurricane Katrina disaster in 2005, populations that are displaced face many difficult challenges. They are forced to leave their home, possessions, and occupations and be separated from their family and friends. Effects from these disasters can have direct impact on these populations' physical and mental health. There is fear of the unknown and loss of control and self-identity. These populations are vulnerable to abuse on many levels, including human rights and gender-based crimes. Although the burdens of a displaced population may be similar, generally they fall into one of two broad groups: refugees or internally displaced populations.

REFUGEES

The United Nations High Commission of Refugees (UNHCR) estimates that there are approximately 12 million refugees worldwide. The role of this commission is to protect and act as an advocate for this population. The UNHCR defines a *refugee* as a person who has a “well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion, is outside the country of his nationality and is unable or, owing to such fear, is unwilling to avail himself of the protection of that country; or who, not having a nationality and being outside the country of his former habitual residence as a result of such events, is unable or, owing to such fear, is unwilling to return to it.”¹ For a person to be considered a refugee, he or she must cross a border into another country. Certain persons are not considered refugees: war criminals, persons who commit acts of terrorism, criminals who have a fair trial and seek refuge to avoid incarceration, soldiers, and economic migrants (those who leave their country on their own will to better their life).

An important principle of refugee law is non-refoulement, which is “a concept which prohibits States from returning a refugee or asylum-seeker to territories where there is a risk that his or her life or freedom would

be threatened on account of race, religion, nationality, membership of a particular social group or political opinion.”²

Refugee status is often considered to be a temporary matter, when in reality it can go on for years to decades. Whole new generations have been born in refugee camps, having no identification with their original country. Generally there are three options for a refugee's destiny: to repatriate to his country, to resettle in the country where he has sought refugee status, or to be resettled to a third country.

INTERNALLY DISPLACED PERSONS

Internally displaced persons (IDPs) may be defined as persons who have been forced to flee their homes to escape armed conflict, generalized violence, human rights abuses, or natural or manmade disasters. They differ from refugees in that they stay within the borders of their home country. It is estimated that the number of IDPs is at least twice the number of refugees worldwide, conservatively being at least 25 million.³ Because they exist within the borders of a potentially hostile home country, they lack the services and protections available to refugees.

PRIORITIES FOR A DISPLACED POPULATION

Although events that lead up to a movement of a large population may differ, there are certain principles that generally apply. Many different actors may be involved in these movements: governments (including multiple countries, states, or localities), military units, and non-governmental organizations. Whenever possible, members of the local community should be involved in the decision to move. This includes government officials, professionals (e.g., public health, healthcare providers, engineers), and the local workforce. These groups can be an invaluable resource in understanding the population needs, potential challenges, infrastructure, and cultural issues. Box 48-1 lists the top priorities of a displaced population. The remainder of this chapter will go through the priorities of the initial management of a displaced population.

BOX 48-1 TOP PRIORITIES

Initial assessment
Measles immunization
Water and sanitation
Food and nutrition
Shelter and site planning
Health care in the emergency phase
Control of communicable diseases and epidemics
Public health surveillance
Human resources and training
Coordination

INITIAL EVALUATION

There should be a clear understanding of the context and what event led to the movement of the population being evaluated. The effects of a war or **genocide** will require very different resources and management than those of a hurricane. Although it can be difficult in the initial assessment, one should try to consider the **potential length of time that this population may be displaced**. Historically, the timeframe is often much longer than one would expect. Remember that there are refugees who have been displaced for decades from their original home, and two-thirds of refugees are still living in camps 5 years later. The **security** of both the population and those responding to the situation needs to be of utmost importance. Unfortunately, at times, this important concept has gone underappreciated or poorly understood.

It is of tremendous value to understand the demographics of the population that has been displaced. This information can be obtained by **initial registration of the population, census information, health records, sample surveys, and speaking with local authorities**. Basic essential data includes the **size, sex, and age distribution** of the population; **family members; cultural makeup** (e.g., **religion, ethnicity**); **medical health, disease prevalence, and vaccine status**; and the identification of potential **vulnerable groups**.

The region where the population is relocating to needs to be well understood. What **resources** are available to the population? Is there an **adequate water** supply, and to what extent can it be used? Will proper **sanitation** be available, and for how long? What amount of **food** is available locally, and what kind of stores are available? Is the land **suitable for living on**? What local supplies are available for constructing **shelter**? What medical care and provisions are available locally? Is there appropriate sanitation? How secure are all these items? What infrastructure is available to bring in further supplies? Are there suitable roads? What size vehicle can the roads accommodate? Are there facilities to repair vehicles that encounter mechanical problems? Are there train stations in close proximity? Where is the closest landing strip, and what is the maximum size aircraft that can land there? Where is the nearest port? If goods are to be shipped in, where can they be stored, and can these items be secured? What are the options to distribute water, food, and supplies in an orderly and safe manner?

Measles

Many healthcare providers are often very surprised to learn that measles continues to be a major cause of morbidity and mortality throughout the world. The pediatric population is at highest risk, and mass vaccination should be highest priority in children from 6 months to 15 years of age.⁴ Measles is a **RNA paramyxovirus** that is highly contagious and is spread through secretions in the respiratory tract. Approximately 90% of susceptible persons will contract the disease after exposure to an infected person.⁵ It should be remembered that **vitamin A deficiency** can cause more severe and complicated cases of measles. All refugee populations should be vaccinated for measles; vitamin A should be distributed when vaccinating.

Water

Water should be top priority in any disaster situation. It is the **cornerstone** of the foundation for an emergency response. Not only is water a necessity for **life**, but also for **basic hygiene**. In the initial response, the quantity of water is more important than the quality. The **absolute minimum requirement of water is 5 liters/person/day**; this should be increased as soon as possible to reach a level of **15 to 20 liters/person/day**. Other things to consider about water include the source, accessibility, location, availability of carrying containers, and security considerations.

Water can be a source of disease on many different levels. Contaminated water, as shown in Table 48-1, contributes significantly to global morbidity and mortality. Freshwater can act as the home for the intermediate hosts that cause schistosomiasis and guinea worm infection. These infections commonly occur when a person stands in water as he or she is collecting it. A lack of water or contaminated water can also contribute to trachoma, which is a major cause of blindness and skin infections. Finally, water can act as the home to insect vectors that cause malaria, dengue fever, filariasis, onchocerciasis, and African trypanosomiasis.⁶ Adequate ways to filter and purify water should be made available.

Sanitation and Hygiene

Besides water, sanitation and hygiene are of top priority in the emergency response. These measures are the first barrier to preventing the spread of fecal/oral disease. On average, humans produce **0.25 liters of stool/day** and 1.5

TABLE 48-1 WATERBORNE DISEASES FROM CONTAMINATED WATER INGESTION

DISEASE	MORBIDITY PER ANNUM	MORTALITY PER ANNUM
Diarrhea	1000 million	3.3 million
Typhoid	12.5 million	>125,000
Cholera	>300,000	>3000
<i>Ascaris</i> infection	1 billion	

liters of urine/day. One can easily see how quickly proper disposal and management of waste can become a problem. When considering a sanitation system, one needs to be culturally sensitive to the population that is being served. It is a futile effort to set up a sanitation system if no one is going to use it. Therefore, it is a good idea to involve local residents in setting up a system. Environmental implications should be considered as well: what impact may it have, how long is it going to be used, and is there any potential to contaminate the water supply? Sanitation systems come in two forms, which are listed in Table 48-2.⁷

Food and Nutrition

The demand for food may lead to displacement. This may occur from a natural disaster or from the effects of conflict and war. Malnutrition is a significant cause of morbidity and mortality in many disasters. It is important to not only remember the direct complications of malnutrition and disease states (Table 48-3), but to understand that many diseases are accelerated or severe secondary to malnutrition—particularly in the pediatric population, where the main causes of death go hand and hand with malnutrition. The following are strongly tied to malnutrition: diarrhea, pneumonia, HIV, tuberculosis, malaria, measles, hypoglycemia, and hypothermia.

The daily minimum nutritional requirement should be 2100 kilocalories/person/day. At least 10% of the calories in the general ration should be in the form of fats, and at least 12% should be derived from proteins.⁸

The caloric demand may be higher based on shelter, environment, burden of disease, and underlying nutritional status of the population. Distributing food equitably is an important aspect of feeding large populations. Ideally, this should be done in a community-based setting in an organized and secure manner. Otherwise, food stores will not be distributed equally. Feeding centers should be established for the severely malnourished.

A food basket for distribution may include wheat flour, rice, sugar, vegetable oil, salt, and possibly local fish or meat. Other supplements may be included for additional nutritional benefit. It is preferable to use local food when available and to encourage the planting of vegetables. Seeds and other equipment can be distributed to the population. Cultural practices and diet also need to be considered. Utensils and fuel for cooking need to be supplied, depending on the food being distributed. Breast-feeding should be encouraged and bottle feeding avoided.

TABLE 48-2 SANITATION SYSTEMS

WET	DRY
Water seal latrines	Trench
Aquaprives	Pit latrines
	VIP latrine
OXFAM Sanitation Unit	Bore holed
	Composting

TABLE 48-3 DISEASE STATES ASSOCIATED WITH MALNUTRITION

DISEASE	DEFICIENCY
Anemia	Iron/vitamin B ₁₂
Goiter/cretinism	Iodine
Scurvy	Vitamin C
Rickets/osteomalacia	Vitamin D
Beriberi	Vitamin B ₁ (thiamine)
Pellagra	Niacin
Ariboflavinosis	Vitamin B ₂ (riboflavin)
Night blindness/xerophthalmia	Vitamin A
Kwashiorkor	Protein

Nutritional screening of the population should be performed to assess particular needs. In general, the incidence of malnutrition in children younger than 5 years of age is used as the general indicator of malnutrition for the population. The weight-to-height index (ideally used), evidence of edema, and the mid-upper arm circumference are means to do a nutritional survey.⁹

Shelter

Depending on the size of the displaced population, several different options may be considered for shelter. With small populations, an attempt may be made to house them with the local population in their homes. As the size grows, this is not possible. Another shelter option is to use existing structures that are already available (e.g., schools, factories, warehouses, and public buildings). Finally, camps can be established for the population to live in. When a camp is being established, considerations on shelter and the site will be based on a number of factors, including type of disaster, size and demographics of the population, anticipated time of displacement (although this is often underappreciated), environmental health risks, terrain, accessibility, available existent structures and infrastructure, climate, security (ideally away from borders), local building materials, and cultural considerations. Table 48-4 lists some general guidelines that are used for site planning.¹⁰

TABLE 48-4 RECOMMENDATIONS FOR SHELTER

CONSIDERATION	SPACE
Area available per person	30 m ²
Shelter space per person	3.5 m ²
Number of people per water point	250
Number of people per latrine	20
Distance to water point	150 m, maximum
Distance to latrine	30 m
Distance between water point and latrine	100 m
	75 m every 300 m
Firebreaks	2 m, minimum
Distance between two shelters	

Medical Care

Medical needs may be anticipated based on the circumstances of the event leading to the displaced population. There are some general principles in responding to the acute medical needs of a displaced population. The goals of the healthcare system should be to treat the common communicable diseases (i.e., diarrhea, respiratory tract infections, measles, and malaria), reduce the suffering from debilitating diseases, afford easy access to the necessary care for the population, deal with the majority of diseases at the basic level, and carry out public health surveillance.

Whenever possible, local healthcare facilities and professionals should be used. A large population can quickly overburden the local system, and often a parallel system needs to be developed. A four-tier model for the levels of healthcare managing the initial acute phase has been repeatedly used with success in reducing excess mortality. The levels include a referral hospital (preferably an already functioning local hospital), a central health facility, a peripheral health facility, and home visits/assessments. A referral hospital is used for more specialized care such as major surgery, obstetric emergencies, and more elaborate laboratory and diagnostic facilities. Patients should be referred to this facility only by one of the other tiers, preferably from the central health facility. Depending on the situation, one central health facility should be present for every 10,000 to 30,000 persons in a camp. This facility should include triage, an outpatient clinic (including minor surgical procedures), simple inpatient services (including uncomplicated deliveries), a pharmacy, and simple laboratory facilities. A peripheral health facility should be established for every 3000 to 5000 persons. Here a simple outpatient clinic or department can treat basic health needs (e.g., dehydration, dressing changes) and refer patients to a higher level of care. At all levels, public health surveillance should be conducted.¹¹

Based on disease prevalence in the population or region, certain medications may be required. In general, “essential” medical kits have been developed and are available from a number of government and nongovernmental organizations. Ideally, healthcare treatment protocols should be established for the more common illnesses. This affords easier management and better treatment when dealing with large populations. It also allows for the anticipation of necessary supplies and medications.

Rehabilitation and Reconstruction

Elizabeth Temin

There are four phases of emergency management:

1. Preparedness: Planning a response to a disaster.
2. Response: Activities that occur immediately after a disaster. These actions are designed to provide emergency assistance to victims. This phase usually lasts a few days to a few weeks.
3. Recovery: Returning the community to normal or near normal. This phase may last for many years.
4. Mitigation: Preventing or reducing the effects of a disaster. This phase should be integrated into the other three.¹

This chapter discusses the third and least understood² phase of emergency management: recovery. There are many factors that go into recovery, for example, the physical reconstruction of homes and public buildings, transportation, and basic services infrastructure, as well as psychological mending of the community and economic recovery of lost time and resources. This stage cannot be considered in isolation because mitigation, the fourth phase, must be integrated into recovery for it to be sustainable.

In 1977, Haas et al³ became the first group to identify and describe the recovery process. They listed recovery as a sequential four-stage model of emergency, restoration, replacement, and development. Current models describe a more fluid recovery process with these stages overlapping and potentially occurring simultaneously.⁴ For example, replacement reconstruction may occur in some locations while at the same time debris clearance occurs elsewhere. Recovery currently focuses on the idea of *sustainable development*,⁴ a concept created by a United Nations Commission in 1986, which refers to recovery as a way to improve the quality of lives and durability of communities.⁵ This has been defined in the World Commission on Environment and Development as “meeting the needs of the present without compromising the ability of future generations to meet their own needs.”⁶ In the short run, it may cost more; better materials may be used, houses and businesses may be relocated, and more stringent building codes and zones laws may be implemented. In the long run, its goal is to protect and strengthen key social and economic infrastructure before disasters strike so as to reduce the likelihood of loss of life and assets⁷ and ultimately improve the community and save money.⁵

There is a vast spectrum of disasters, and the process of disaster recovery can adapt the available tools to fit the specific situation. It is useful to apply a framework in thinking about the similarities and differences in disasters. They can be categorized as natural or manmade, sudden onset or slow onset. Examples of natural disasters that are slow onset are droughts or epidemics such as severe acute respiratory syndrome (SARS); sudden onset examples are floods, hurricanes, and earthquakes. Examples of manmade disasters that are slow onset are wars such as the war in Iraq, and sudden onset examples are bombings or terrorist activities such as the Sept. 11, 2001, attacks and the Exxon Valdez oil tanker spill in 1989. In general, the important differences are the duration of the impact and the severity of direct and indirect effects. *Direct effects* are defined as the physical destruction and lives lost as a result of the disaster. *Indirect effects* are the work time lost, jobs lost, and the change in spending in the community involved.

There is also a framework in which to categorize recovery; it can be designated as vertically or horizontally mediated. *Vertical mediation* recovery refers to the hierarchy of local communities, the state government, and the federal government. *Horizontal mediation* refers to the network of groups within a community. Every recovery and management process needs a balance of both vertical and horizontal mediation.

The next three sections of this chapter discuss how certain communities and countries have handled disaster recovery historically, how the United States currently handles disaster recovery, and finally, pitfalls that are common in recovery efforts.

HISTORICAL PERSPECTIVE

The literature on disaster recovery discusses both man-made and natural disasters but has primarily been only descriptive. When the Tsarist regime in Russia was overthrown in 1917, there was an almost complete nullification of all property rights, and the black market became the form of informal barter. Industrial production fell to 20% of pre-war levels by 1920.⁸ Hyperinflation occurred, impeding the ability to rebuild the country.

In Hamburg, a series of raids over a period of 10 days in 1943 destroyed almost half the buildings in the city.

In the aftermath, there were as many injured as fatalities, and over two thirds of the city's hospital beds had been destroyed. Over a period of months, 300,000 refugees were rehoused and 500,000 permanently evacuated. Adequate water supply was a problem even though wells had been dug prior to the event. Yet within 5 months, Hamburg had recovered up to 80% of its former productivity.⁸

In 1945, the atomic bomb was dropped on Hiroshima. Deaths were estimated at 80,000, and almost 70% of buildings were destroyed. In this case, recovery took much longer. It was only by 1949, 4 years later, that the population had recovered to its former numbers and 70% of the destroyed buildings had been reconstructed.⁸

In 1982, Marin County experienced continued floods and mudslides until finally a presidential disaster was declared. Federal teams had trouble appropriately identifying local public priorities from the myriad of recovery issues. As an example, the Intelligence Hazard Mitigation Team identified two sites for priority attention. County officials indicated that those were not the priorities they would have selected.¹ Damage survey reports were begun in over 300 sites, and many were held up by disagreements over the definition of a *mudslide* versus a *landslide* and how to define *repair* versus *permanent restoration*. Each of these occurrences receive different levels of funding.¹ On the positive side, Marin County actively included mitigation into recovery efforts. They created landslide-protection zones and required that prospective home buyers receive mandatory notification of stability problems.¹

In 1988, Jamaica was hit with Hurricane Gilbert. This was the first direct hit with a hurricane in more than 35 years. As a result, Jamaica had been in a period of complacency with a low sense of preparedness and concern for mitigation. Nineteen of the 33 watershed areas had been eroded by deforestation and the expansion of agriculture onto high-slope areas. When Hurricane Gilbert struck, there occurred not only the destruction from the hurricane but also subsequent significant flooding and landslides. Many Jamaicans lived in highly vulnerable locations. The low-income housing in the area that was not built up to the housing codes, and those in floodplains and gullies suffered predominantly.⁹ It was estimated that 20% of all housing was damaged and 2% destroyed.⁹

In 1989 when the Loma Prieta earthquake hit Santa Cruz County, the local community was strong. When the Federal Emergency Management Agency (FEMA) came and set up a disaster assistance center (DAC) in the city of Santa Cruz, the citizen leaders requested a satellite DAC to support the rural population. FEMA accepted the request after determining that a significant number of families had been overlooked in their initial assessment. By working together, the community and the federal government were able to adequately support the victims of this disaster.²

CURRENT PRACTICE

In the United States, recovery planning started in 1803 when local resources were overwhelmed during a fire in Portsmouth, New Hampshire. The local government

asked Congress for help, creating the first legislative act for federal resources. In 1950 the first permanent and general legislation, the Federal Disaster Act, came into existence. This was revolutionary because it was the first Act to create a general response to all disasters. Before this, each disaster resulted in Congress passing a new localized piece of legislation. In 1979, President Carter pulled all the distinct response groups together along with the military resources to create FEMA.

In 1988 Congress passed the Stafford Act, which focused FEMA toward hazard mitigation and coordination of disaster recovery programs. The Disaster Mitigation Act of 2000 established specific requirements for hazard mitigation planning, and grants became available to allow local and state governments to use mitigation funds for pre-disaster planning.⁶ In 2001 the actions of Sept. 11 pushed Congress to create the Department of Homeland Security, which was the largest reorganization of federal agencies since the Great Depression.⁶

The magnitude of disaster recovery depends on the magnitude of the destruction. In a small local disaster, volunteer organizations such as the Red Cross and private insurers may be enough to aid victims. When a disaster overwhelms the recovery forces of a community, that community can turn to the state government, and ultimately to FEMA, for resources. Within the first 48 hours of a disaster, an assessment team should provide an initial assessment of the damage. This includes identifying immediate needs such as food, shelter, and infrastructure. A preliminary damage assessment by the local government will determine whether federal aid may be needed and should be requested. Once the immediate needs are identified, and if federal aid is requested, a second, more in-depth survey should be done by FEMA. This second survey should include asking the plans of the displaced citizens: Do they plan to move, or rebuild in the same spot? Public infrastructure, sewers, and storm drains should be examined. What about the town? What was there before the disaster? What currently exists? Were there any existing plans for expansion of the area that could be used for rebuilding? What are opportunities looking at the long term?¹⁰

Every U.S. state maintains an Emergency Management Agency (EMA) and an Emergency Operations Plan. Their role is to establish and maintain an emergency program concerned with preparedness, response, mitigation, and recovery; to coordinate and train state and local governments; to recommend whether federal aid is needed in the case of a disaster; and to coordinate state and federal resources and act as an intermediary between local and federal groups.⁶ In the past, the majority of these plans have been concerned primarily with the short-term response.² Recently many states have been trying to adapt to a more long-term response.

When a disaster, whether natural or manmade, strikes a community in any part of the United States, including the Virgin Islands, Guam, U.S. Samoa, and the commonwealth of the Northern Mariana Islands,¹¹ if that state is overwhelmed and state resources are not enough to provide aid, the federal government may declare a disaster under the Robert T. Stafford Disaster Relief and Emergency Assistance Act.¹¹ In 2000 there were 45 major

disaster declarations made in 31 states and the District of Columbia.¹² These disasters ranged from tornadoes to wildfires to winter storms. Initial response resources include food, water, emergency generators, and the mobilization of specialized teams (e.g., search and rescue, medical assistance, damage assessment, and communications). For more long-term relief, there are loans and grants to repair or replace housing and personal property, roads, and public buildings. There is also assistance for mitigation opportunities, counseling, and legal services. These services are outlined in the Federal Response Plan (FRP), which describes the policies and plans of 25 federal departments and the U.S. Red Cross.¹¹ The FRP can be implemented in conjunction with other specialized groups including plans for telecommunications support, the National Oil and Hazardous Substances Pollution Contingency Plan, the Federal Radiological Emergency Response Plan, and the Terrorism Incident Annex.¹¹ In addition to the FRP, some federal agencies have the authority to provide disaster aid even when the magnitude is not sufficient for the president to declare a federal disaster, including the Department of Agriculture, Department of Commerce, Department of Housing and Urban Development, and the Small Business Association (SBA). The FRP employs a multiagency operations structure based on the Incident Command System (ICS). (See Chapter 30, The Incident Command System.) Disaster Field Offices under the Department of Homeland Security may be created along with a national emergency response team. Recovery efforts are the responsibility of logistics and administration teams within the disaster field offices.

The first source of insurance for all homeowners, businesses, and towns is private insurance. If that is not adequate or not available, the next action should be to register with FEMA by the stated deadline, usually within 2 months of the disaster. After individual private insurance carriers, the SBA provides the next largest portion of aid. All those above a minimum income are referred to SBA and should apply for SBA loans.¹⁰ The loans must be repaid, but they carry low interest rates. These loans include:

1. Home disaster loans to homeowners or renters to repair personal property;
2. Business physical disaster loans to businesses to repair or replace property including real estate, equipment, and inventory (not-for-profit organizations are also eligible);
3. Economic injury disaster loans to small businesses and agricultural cooperatives to replace working capital.¹⁰

FEMA also offers three types of assistance:

1. Individual and family grants: These loans are granted to persons with needs not met by private insurances, SBA, or volunteer organizations. These grants are for basic needs only, not to return life to normal. Costs can include medical and counseling assistance, housing repair, funeral expenses, and insurance premiums.
2. Public assistance: This program gives aid to local governments for emergency services and the repair or

replacement of public facilities, for example, the removal of debris, repair of infrastructure, or emergency protective measures. It is often the most costly element of recovery, and typically the cost is shared with the state in a 75%/25% split.⁶

3. Hazard mitigation grant program¹⁰: These grants are used by the federal, state, and local governments to incorporate mitigation into the recovery process. Actions may include acquisition of homes, public education, and retrofitting structures to better resist subsequent disasters such as floods and hurricanes. Cost will be shared between federal and state resources.⁶

Businesses have special considerations in light of a disaster. The primary objective of recovery planning is to enable an organization to survive a disaster and to continue normal business operations. To survive, the organization must ensure that critical operations can resume/continue normal processing and minimize the duration of a serious disruption to operations and resources (both information processing and other resources); a premade contingency plan is the best method of accomplishing this.¹³ Specific measures may include having an alternate site of operations if the current facility is damaged, storing vital documents off-site, and having an alternative energy source such as a generator. Larger businesses may be better able to withstand a disaster because assets and the workforce may be dispersed across a wider geographical area.⁶

A disaster is a life-altering event. Survivors share an enormous experience and come to view the world around them in new and different ways. Seeking help from the government, voluntary agencies, and insurance companies can be long and frustrating, which may only compound the feelings of helplessness. Anger and further despair are common. Mental health staff may assist persons by reassuring them that this “second disaster” is a common phenomenon¹⁴ and that they are not alone in their frustration. Many people may not want to seek formal counseling, either because of the stigma some still associate with psychiatric help or because they are unwilling to take time away from putting their lives back together or helping others. Very effective mental health assistance can be provided while the worker is helping survivors with concrete tasks. The “over a cup of coffee” method of informal intervention may be the best method to help. For example, a mental health worker can use skilled but unobtrusive interviewing techniques to help a survivor sort out demands and set priorities while they are jointly sifting through disaster rubble.¹⁴

Although having community involvement is beneficial to the process of recovery, it is also very important for the mental well-being of the community. Failing to involve the community can lead to resentment and fragmentation. The inhabitants may be unhappy when aid is not appropriate to the community’s perceived needs, and this insult may be compounded if they are then labeled unappreciative of the federal help. When people have a hand in their own recovery, they feel empowered and will increase their involvement. This leads to a stronger community network that in turn increases the ability to provide self-help.

In general, there are two broad problems with disaster recovery: too little horizontal planning or too much dependence on vertical aid. The pitfalls occur when the horizontal and vertical planning are not balanced.

In the case of too much dependence on vertical planning, the community does not contribute anything to the recovery process and the government organizations and nongovernmental organizations dictate the recovery plans. In the past, these groups have come in with the intention of “fixing” the situation. This is referred to as “top down” theory.⁹ In addition to not providing the optimal care, this may impede the self-sufficiency of these disaster-struck areas. Assumptions may be made, including the following: (1) the victims are a burden; (2) the host government is weak and cannot manage alone; (3) foreign aid organizations don’t require accountability; (4) aid for the victims reflect the defined needs of the victims (when, in fact, the aid reflects the projected need by the donor).⁹ An example of this last point was when Hurricane Hugo struck Montserrat in 1989. Ninety-eight percent of all homes were affected, 50% severely and 20% completely destroyed.⁹ The Peace Corps brought in large numbers of prefabricated housing to replace all the destroyed homes. Although they were able to help a lot of people numerically, the homes they provided had two-sided pitched roofs instead of the typical Caribbean four-sided roofs that were better able to withstand tropical winds. They also did not have an interior design to allow for cross ventilation. The early recipients of the homes reported this finding to the Peace Corps, but the Peace Corps was unable to change the design. Though well intentioned, the Peace Corps was predominantly meeting the need projected by the donors instead of the actual needs of the victims.⁹

Overdependence on vertical planning can also result in a lack of accountability and thus uneven recovery results. In Jamaica, after Hurricane Gilbert, the primary housing aid program was the Building Stamp Programme, which was set up by the Jamaican government, the World Bank, Canada, Germany, Japan, OPEC, and the United States. Homeowners were issued building stamps based on the extent of damages and financial need. These stamps would then be redeemed only at building supply stores who were members of the Jamaican Hardware Merchants Association for building materials, including zinc sheets, nails, and lumber. Squatters and renters were not eligible for stamps and were left without any recourse for finding aid. People who were not at home during the time of the survey were not listed as needing aid.⁹ Additionally, it was found that the stamps were distributed unequally. As a result, many needy people were left without any support.

There is always the risk of creating a “dependency syndrome” by not thinking of sustainable development when investing money and effort into the recovery process.⁹ This occurs by the replacement of homes and infrastructure that are likely to be destroyed by subsequent disasters or that do not benefit the town, resulting in the need for continued care for each disaster. Instead of being able to learn from prior occurrences and create a more resilient

town/infrastructure, the same mistakes are repeated over and over again. For example, Jamaicans used the stamps to fulfill daily needs such as mattresses and utensils and did not spend time reinforcing their homes against further hurricanes or floods. When the next hurricane hits, these people will have the same destruction to their homes as occurred with Hurricane Gilbert.⁹

In the case of too little horizontal planning, the results may be a chaotic lack of cooperation between groups and potential leaders. Studies have shown that many community plans focus primarily on the emergency period and do not give adequate attention to recovery and reconstruction. If there is a plan, it often exists on paper only and in the case of an actual disaster it is not used. In fact, many officials are not aware that a plan exists.⁴ These flaws lead to chaotic implementation of an ad hoc recovery. The community lacks the ability to work together and thus fragments and cannot unify to control its own affairs. As a result, the redevelopment is likely to be inadequate to fulfill the needs of the community. If there is aid from government and nongovernmental groups, they are sometimes uncoordinated, either duplicating actions, leaving areas without any aid,⁴ or giving aid that is inadequate for the needs of the area. In Saragossa, Texas, a small isolated community that was devastated by a tornado in 1987, there was no local government in place at all. When a disaster advisory board was created, it was done without any input from the local inhabitants. The outcome was that the Saragossans considered themselves worse off 2 years after the tornado than they had been beforehand, both because of the quality of the rebuilt neighborhoods and because they felt they were looked on as helpless and ungrateful.²

Studies in the Caribbean have shown that the different power levels in an uncoordinated community may lead to powerful interest groups pressuring public authorities to rebuild first in areas in which they have the greatest interest. Poorer neighbors with weaker ties to public authorities will get delayed care.²

In the United States, vertical planning predominates because few communities have detailed plans in place and because they may not have the financial reserve to pay for the recovery. When a plan is in place before a disaster, it allows for a strong horizontal network. Then, when a useful vertical element is added, the results can work wonders. By 1975 recurrent floods had repeatedly decimated the town of Soldiers Grove, Wisconsin. Each time they rebuilt. At one point they added a dam, and they planned for a levee but were unable because of financial restrictions. They decided they would take the funds allocated for the levee and use it to plan for town relocation. Although federal funds were slow in coming, they did create a plan. In 1978, when the largest flood in the history of the area occurred, they were ready with a fully written strategy. When they were granted funds for reconstruction, they put their plan into effect. Not only did they relocate out of the flood plain to prevent recurrence of this destruction, but they decided to create a town that was 75% solar powered.⁵ Because they had had the luxury of time in the planning stage, they had asked each business owner where they wanted to be located and how they wanted their business to be built.

As a result, the town became not only exactly what the community wanted, but its creation instilled a great sense of pride and satisfaction in its citizens, thus creating a happier community as well.

Disaster Education and Research

Kenneth A. Williams, Leo Kobayashi, and Marc J. Shapiro

Disaster education, regardless of the audience, has two goals: (1) prevention of disasters, and (2) mitigation of disaster effects, including improved outcome for victims and safety for responders.

Disaster education should be based on principles of adult education and valid research. Education competencies and design should go hand in hand with the design and implementation of disaster research. Unfortunately, most current disaster research is descriptive and not relevant for education planning.

For the general public, disaster preparedness once consisted of personal knowledge. People tended to know their limitations and had familiarity with the risks inherent in local activities and trades. Technological advances have both protected the population in developed countries and increased the risk of extraordinary catastrophe. Disaster research and education must address these changes in order to remain relevant.

HISTORICAL PERSPECTIVE

Various public health triumphs mitigated epidemics and disasters through the years. Dr. John Snow,¹ after brilliant but straightforward epidemiologic investigation, mitigated a cholera epidemic in 1855 by simply removing the handle from the contaminated pump. Hygiene, antibiotics, and field medicine saved countless lives. However, disaster response remained largely an uncoordinated humanitarian effort.

The dictum that there were “no rules” in a disaster became an excuse for response failures and deficient education and planning. Although disasters overwhelmed local response capability, certain types of disasters recurred, and response strategy could therefore be formulated. Subsequent efforts to plan for disaster response were well intentioned but failed because they diverged from daily practice. Complex plans involving communication,² patient identification and documentation, and command systems that were literally pulled from cabinets or trailers only for annual drills failed in actual events. The military has learned that soldiers “fight like they train,” and they train frequently. Disaster responders need to learn this lesson; disaster response paradigms fail in proportion to their deviation from daily practice.

CURRENT PRACTICE

Education

Adequate disaster education should include age-appropriate guidelines and must follow a basic format for training that allows evaluation of effectiveness. One recommended format is the establishment of clearly stated objectives (e.g., “The children will be evacuated from the school in under 5 minutes,” or “The physicians will properly recognize nerve agent exposure from symptoms presented during simulation.”). These objectives are next used to develop evaluation tools (e.g., a timed drill for the school, written testing or observed performance for the physicians). Training curricula are then developed to achieve the desired objectives as measured by the evaluation tool. The students, for example, may need little more than general principles (“Follow the teacher’s instructions in an emergency”) and awareness that the alarm bell signals such an emergency; therefore occasional drills may suffice to maintain the needed level of training. Physicians treating patients exposed to chemicals may be trained using a variety of adult learning techniques.

Target audiences for disaster education include the general public, nonmedical responders, and medical responders. The same principles of effective education apply. General public topics include general disaster readiness, sheltering, evacuation, and first aid. Such education can reduce panic, minimize load on evacuation or shelter systems, and mitigate illness and injury. Nonmedical responder topics vary with the type of responder but should include awareness of medical response issues and plans. Nonmedical responders may include those who provide shelter, evacuation, security, law enforcement, administration, logistics, food and water supply, sanitation systems, transportation, and structural engineering, among many others. Medical responders should improve their readiness through training; including knowledge of education provided to the general public and nonmedical responders. This inclusive and coordinated approach will optimize readiness, prevention, and mitigation.

Readiness is the ability to perform, on request, a specific action in the allotted time. To improve readiness, an agency may work on communication essential to notify personnel of a request for service and coordinate their

actions, optimal performance of specific tasks, or means to increase the efficiency of performance. Each of these areas can be the subject of a variety of types of research and training and can apply to the general public and non-medical responders as well as medical responders. For example, is a population ready to evacuate? Are the regional water suppliers ready to secure their facilities and prevent an effort to contaminate public drinking water? A variety of research exercises linked to training programs can improve readiness in such areas.

Communication, a common challenge in disaster response, can be improved with use of robust and redundant technology that is familiar to all users. Practical research can assist agencies in the selection and adoption of flexible communication systems likely to remain functional during disaster events. Research parameters for such systems might include features such as interagency interoperability, simplicity and flexibility of use, sufficient power source and range for anticipated events, and the ability to move data between variable system elements. Drills, technical demonstrations, and prospective data-gathering during real events are some research methods for the evaluation of communication systems.

Similar to readiness, prevention may encompass public health, engineering, zoning, security, or other measures that trap errors that would otherwise, in certain circumstances, lead to disaster. In some cases, a disaster (defined as “an overwhelmingly damaging event”) may result in few if any medical casualties. Loss of computer data, defective products, and financial crisis are a few events that can have disastrous results without illness or injury, depending on those affected. Nevertheless, “atraumatic” disasters should be considered in disaster planning, education, and research alongside casualty-producing disasters, at least for healthcare systems if not for all community entities. The disruption caused by a loss of computer data, by revelations of administrative scandal, or by bankruptcy of a relied-on local service can be significant and can create stress and damage comparable to an event that causes injury or illness.

There are many models of adult education that can be used to train disaster responders: self study, distance learning, direct education, hands on learning, drills and exercises, and, most recently, simulation labs. The types of education must be matched to the audience as well as the task to be taught and must also take into account available resources. For example, although the best method of teaching personnel how to do a particular skill may be intensive hands-on experience, there may not be the time or money for large audience training of this type. Types of education include the following:

- Self-study: Involves self-paced learning, either from a text or Internet source. This kind of learning lends itself well to those with limited downtime during their workdays and with time to study that may be off shift or off hours.
- Distance learning: Currently well used by the U.S. Centers for Disease Control and Prevention, this type of learning is often accomplished by a satellite broadcast. It allows many to be trained in a “live environment” where their questions and issues can be addressed.

- Direct education: This involves a lecturer delivering content to a reasonably sized audience. Although this type of education facilitates questions and feedback to participants, it requires a ready pool of expert educators that may not exist in a particular subject or geographic area.
- Hands-on learning: Particularly suited for teaching skills, such as the wearing of protective equipment, this training is labor and time intensive and requires the use of local expertise and small class size-to-instructor ratio.
- Drills and exercises: Although the full-scale exercise with its cast of thousands is usually seen as the ultimate training experience, much can be accomplished by specific, task-oriented drills. Drills and exercises are an excellent place to solidify training, identify future needs, and conduct research.

Simulation Training

Human patient simulation is reaching a larger audience as the technology has improved and become more accessible. Distinct from the training offered by cardiopulmonary resuscitation manikins or personal computer-based multimedia software, high-fidelity medical simulation features integrated life-sized “patients” with programmable, reproducible, and physiologic response capabilities. Interactive communication, the ability to undergo procedural interventions, and real-time recording of events are key features. The application of these tools and techniques to disaster medicine education is now taking place.

Both manikin and virtual reality (VR) simulated patients have been implemented to train healthcare personnel in various fields. Detailed patient presentations in realistic treatment settings, accurate modeling of human physiology, and dynamic changes in response to interventions are contributing to unique educational experiences. Otherwise unachievable training is being made possible for clinical events and care settings that harbor significant risk and enormous consequences. Difficult medical resuscitation and intraoperative crisis management are representative subject areas.

Manikin-based systems such as those using the Laerdal SimMan and METI HPS models are becoming widespread due to the relative ease of setup and maintenance compared to VR counterparts. Expanding from their original role in anesthesia and resuscitation instruction, these manikins are being applied to disaster training in an ongoing exploration of their capabilities. Re-creation of the physical barriers and material impediments to patient care at disaster scenes is a prime area of inquiry. For example, practicing of intravenous access, medication administration, and endotracheal intubation while garbed in personal protective equipment (PPE) is currently being investigated on manikins.³⁻⁶

Total-immersion virtual reality (TIVR) and associated technologies are also starting to be used for disaster education.⁷ Featuring fully computer-generated environments and patients with multisensory interactivity (i.e., visual, auditory, haptic), TIVR advances the “perceptual illusion of non-mediation.”⁸ This capacity to seamlessly establish the presence of participants within the TIVR-constructed world hints at the potential for tremendously flexible and virtually unlimited simulations for training. A case study in

this endeavor is the University of Michigan 3D Lab, where researchers have implemented a disaster scenario inside a Cave Automated Virtual Environment.^{9,10} Additional examples are present at the University of Missouri–Rolla¹¹ and the University of Padova.¹² Lack of standardization and significant startup requirements limit TIVR's accessibility for the time being.

Civilian and Commercial High-Fidelity Simulation Applications in Disaster and Weapons of Mass Destruction Education

With the increasing number of civilian sites featuring various forms of patient simulators, training courses have begun to earnestly delve into disaster-specific content. The fundamentals of disaster medical response, such as situational and hazard assessment, triage, patient examination and treatment, decontamination/provider protection, and evacuation are being addressed.¹³ Focused task training as well as exercises fostering specific cognitive processes and teamwork behaviors^{14,15} is being undertaken.

Increased funding for disaster and weapons of mass destruction (WMD) training has helped prehospital systems in several states experience sophisticated disaster exercises employing advanced medical simulation. These efforts in Florida, Maryland,¹⁶ and Rhode Island¹⁷ have been primarily based at university-affiliated academic simulation centers receiving state and/or federal support. Significant use of high-fidelity simulation technology for nuclear, biological, and chemical preparedness is most apparent internationally in the Israel Center for Medical Simulation's activities. Their programs address the preparation of physicians, nurses, and paramedics for the casualties of nonconventional warfare.¹⁸⁻²⁰

In the commercial sphere, at least two U.S. centers are offering courses using high-fidelity manikin patient simulators for training in WMD and hazardous materials (HazMat). Simulation Training in Emergency Preparedness courses²¹ supported by the Health Resources and Services Administration are in progress at the Rhode Island Hospital Medical Simulation Center. The Texas Engineering Extension Service provides another WMD-focused prehospital operations and planning curriculum.²² These courses for the emergency medical service (EMS) community contain assorted applications of patient simulation, ranging from isolated patient care duties to full-scale multi-manikin disaster drills.

Military high-fidelity simulation applications in disaster and WMD education military forces have routinely been involved in training for disasters, either in support roles for natural calamities or in combat preparation duties. Consequently, many of the issues raised by terrorism and WMDs have been addressed by the military in their established training. Troops engaging in combat have been expected to encounter weaponized chemical toxins, bio-weapons, explosives, and radioactive hazards. Whereas the settings in which such exposures can occur have changed, the knowledge and techniques involved in responding to them remain mostly unaltered.

The U.S. military is developing and running training programs focused on the healthcare services specialist,

known as a "91W," with a particular interest in chemical, biologic, radioactive, nuclear, and explosive qualifications.²³ Component modules include personal computer-based Simulation Technologies for Trauma Care (STATCARE)²⁴ and Nuclear Biological Chemical Casualty Training System (NBCCTS)²⁵ software. Advanced patient simulation within the various project efforts features prominently under the Medical Simulation Initiative. Several hundred high-fidelity manikins in on-site and distance-learning settings have already been integrated into 91W training at various locations.²⁶⁻²⁸ WMD-specific applications are being phased in. Additionally, logistical simulation of the mechanics and delivery of medical care at multiple levels in a realistic and complete battlefield environment is progressing with the Combat Trauma Patient Simulator program.²⁹

Future Directions in Simulation

Numerous simulation experts and groups are pursuing scientific validation of simulation techniques in healthcare education. The disordered environment of a true disaster make prospective, controlled, and objective studies of educational content transfer difficult. Retrospective analyses may have a role, whereas surrogate markers of training efficacy and improvement in emergency preparedness could serve to demonstrate simulation utility in the interim.

Enhancement of independent disaster response abilities can be individually assessed at "skill stations" akin to those in advanced cardiac life support courses. Global rating scales have surfaced as potential indicators of overall learner competence in educational settings using high-fidelity simulation.³⁰ Such instruments, using properly defined scoring systems, should help in investigating basic disaster response competencies in conjunction with fully immersive multiple-manikin disaster drills.

Development and testing of tools to demonstrate improved medical responder preparedness with proper disaster training are taking place through federally and state-funded projects. Extensively incorporated into these activities, high-fidelity simulation has already allowed objective examination of EMS providers' scene hazards assessment, triage decision-making, use of novel interventions,³¹ and resuscitative actions¹³ in PPE. Continued work through such ventures is hoped to establish causal associations between high-fidelity simulation training, enhanced responder readiness training, improved disaster medical response, and ultimately, better patient outcomes.

The greatest challenge for disaster trainers is to maintain the training competencies and certifications initially acquired and to work on continual skill development in an environment where little is changing, and the next disaster may seem far away.

CATEGORIES OF RESEARCH

Disaster research can be categorized and associated with educational objectives. Categories include after-action report/case studies; aftermath epidemiology; discussion of planning, training, and mitigation techniques; trials of specific techniques or equipment; organizational or analytical schemes; and randomized controlled trials.

After-Action Report/Case Studies

A description of the first 10 cases of anthrax in the United States caused by a terrorist event³² provides an example of the after-action report/case study. These data are useful in planning response magnitude and type. Recurring failures in response are well elucidated in this type of report. While cogently documenting the events surrounding various natural and manmade tragedies, these papers also often report shockingly similar response failures, including those involving communication, logistics, clothing, equipment, interagency cooperation, perimeter control, patient care delays, and suboptimal distribution of casualties.³³ Although various nonmedical entities such as the Federal Aviation Administration and National Transportation Safety Board have implemented various regulatory and technology improvements during the past few decades, reducing the incidence of manmade disasters and mitigating their severity, medical responders often face the same challenges reported 25 years ago.

Aftermath Epidemiology

Descriptions of the delayed effects of a disaster point out needs for subsequent responders and planners. The need to rapidly reestablish infrastructure, to attend to chronic healthcare needs and sanitation, to distribute medications, etc., can all be noted in a review of these research papers. Additionally, descriptions of lingering effects, such as the description of eye injuries following the Tokyo sarin attack, can be illuminating. Cultural diversity may alter the expression of disaster effects, but awareness that disasters have long-lasting and significant effects can be important for planners and educators seeking to address these concerns.

Discussion of Planning, Training, and Mitigation Techniques

A discussion of planning, training, and mitigation techniques might include a survey and discussion related to bioterrorism training for emergency medicine residents.³⁴ These papers document current education and planning methodologies and are useful in two ways. First, they provide a benchmark for the schemes in place that can be compared with outcome when an event occurs. If a system has a plan in effect, with specific training methods and specific techniques, readiness (as measured in a well-run drill or an actual event) can be compared with alternative systems. Second, these papers serve to distribute the ideas, good and bad, that others have developed. Planners should be familiar with this literature and should seek to learn from the mistakes and brilliant insights of others as they design training and response plans.

Trials of Specific Techniques or Equipment

Although fairly rare in the disaster research literature, trials of specific techniques or equipment present various methodologies for care and use of equipment. Topics such as triage technique, categories of patient condition, patient identification tags, communications equipment,

training programs in specific scenarios or problems, and command structures fall into this literature category. A weakness of many of these papers is failure to document use of the topic item (method, equipment, etc.) in a real event or in a controlled series of drills where it can be realistically compared with an alternative. Papers that tout the utility of an item and offer only a single drill designed to showcase the item should be scrutinized carefully and critically.

Organizational or Analytical Schemes

Organization and analytical schemes discuss progress in disaster management, or lack thereof, and offer schemes or suggestions to improve international coordination, planning focus, funding allocation, etc.³⁵ They often report the collective wisdom of a group of experts, but occasionally offer the scheme of a single person. In either case, this body of literature should be familiar to all disaster researchers and educators because a certain level of standardization and commonality in definitions and language is essential to collaborative effort.

Randomized Controlled Trials

Vanishingly rare in disaster research, randomized controlled trials are nonetheless very important. The potential to perform research on recurring disasters (e.g., floods, earthquakes, certain transportation disasters) exists, and a few researchers have attempted to gather data comparing use of techniques or equipment with some degree of randomization.

Currently, the most feasible option is the use of recurring drills to conduct research. The Rhode Island Disaster Initiative (RIDI), a federally funded disaster research project that began in 1999, included a series of disaster drills performed in a high-fidelity multiplace simulation center. The ability to accurately reproduce a disaster drill allowed the RIDI team to compare training and equipment practices between randomized responder groups. Future initiatives should move this type of research into formal research formats, such as crossover control or randomized trial models.

Practical Applications of Disaster Epidemiology

P. Gregg Greenough and Frederick M. Burkle, Jr.

Regardless of whether a prolonged heat wave hits Europe, a spate of hurricanes occur in the southeastern United States, a volcano erupts in the Philippines, or a complex humanitarian emergency continues in Sudan, each type of disaster has a unique epidemiology. Broadly, *epidemiology* refers to the study of the distribution and determinants of health-related states or events in specified populations and the application of this study to managing and controlling health problems. In essence, epidemiology uncovers the way in which specific disasters generate specific predictable patterns of public health effects, usually disease or injury, in dimensions of time, space, or subgroup within a population.¹

Disaster epidemiology has a role in every aspect of the disaster cycle, including the development of prevention strategies, the assessment of need and targeting of resources during the impact phase, and the measurement of the effectiveness of the disaster response. Every type of disaster can be classified both as a “disease process” and as a “disease generator.” Knowing the types of public health effects of a given disaster can guide disaster preparedness efforts. For instance, a population prone to earthquakes will present acutely en masse to emergency departments with fractures, closed head injury, lacerations, and soft tissue injury. Within days, patients may be at risk for complications such as renal failure and wound infection. Long-term effects such as mental health issues and disability will be public health problems well after the event itself. Advanced understanding of a specific disaster’s epidemiology can assist disaster managers and organizations in planning for a disaster response and directing critical resources before, during, and after the event. More importantly, disaster mitigation efforts guided by epidemiology can reduce the number of deaths and minimize the burden of disease caused by a given disaster.

Epidemiology plays a role in the developing world where basic healthcare is lacking, preventable infectious diseases are endemic, famine is recurrent, and subsistent-level poverty the norm. High mortality rates can be expected in places where disasters are superimposed on a baseline poor public health infrastructure. Populations displaced by natural or human-generated disasters are at risk for health, food, water, and shelter insecurities.

HISTORICAL PERSPECTIVE

Epidemiology, which once simply concerned itself with infectious diseases and their relation to a population, has evolved over the years to comprise all hazards that affect the public health, including natural and human-generated disasters. The practical application of epidemiology began with the humanitarian assistance during the Nigerian (Biafran) War of the late 1960s and a variety of natural disasters in the 1970s (e.g., Bangladesh cyclone, 1972; Guatemala earthquake, 1976) and 1980s (e.g., Armenian earthquake, 1988).^{2,3,4} These events showed that epidemiologic methods could measure and minimize risk, assess the relief effort, describe patterns of morbidity and mortality, and suggest prevention and intervention strategies. To that end, the Center for Research on the Epidemiology of Disasters (CREDE) at the University of Louvain in Belgium was created in the early 1970s; today it maintains a global emergency events database (EM-DAT) that provides information on the effects of the nearly 13,000 mass disasters since 1900. The existence of such a database allows for donors, disaster managers, researchers, and policy makers to make comparisons across disaster type and place and analyze vulnerability factors.

Historically, large numbers of humanitarian relief and multilateral agencies with varying degrees of expertise in humanitarian response did not approach the humanitarian response in a unified, coordinated fashion. However, with the advent in the late 1990s of the Sphere Project, a collective effort of humanitarian nongovernmental organizations (NGOs) and the International Federation of the Red Cross and Red Crescent Societies to reach consensus on minimum standards in health, food, nutrition, shelter, water, and sanitation, a common understanding of the role of epidemiology in supporting the public health in disasters emerged.⁵

CURRENT PRACTICE

Epidemiologic studies in disasters need to be proactive, timely, well-designed, and widely disseminated to all organizations involved in all phases of the disaster cycle.

In addition, the epidemiologic method used should be appropriate for the public health issue in question. The following field methodologies are the keys to critical information during all phases of the disaster.

Vulnerability Analyses

The key purpose of vulnerability analyses is to identify populations at risk in an effort to implement preparedness and mitigation efforts as well as establish a baseline from which rehabilitation efforts can be measured. Thus, a variety of stakeholders—from disaster managers to urban planners to insurance representatives—find such information vital to their respective tasks. A more detailed discussion can be found in Chapter 17; the brief mention here is to highlight the role of epidemiology in the analysis.

Vulnerability is defined as the degree to which one's life and livelihood (or that of a population) is at risk by an encounter with a given hazard. The hazard is the potential for a specific harm-causing event which may directly or indirectly affect the population.⁶ Vulnerability is not only measured by degree of exposure of the hazard but also by the level of sensitivity and resilience of the population's environment, or what is increasingly being referred to as the *coupled human-environment system*.⁷ Changes in a population's environment affect its ability to absorb the shock of the hazard. Factors inherent in the system's ability to absorb the shock and stresses of a given hazard or combination of hazards may include the level of environmental degradation and deforestation present, the degree of urbanization, the population's socioeconomic status, and the types of livelihoods on which the population depends. On a macro level, transnational factors such as global climate change and debt-relief policies or national factors such as types of national land use planning and degree of communication and transportation infrastructure, degree of governmental stability, and adherence to the rule of law all directly contribute to a given population's vulnerability. All of these factors are potential epidemiologic markers in a vulnerability analysis.

Risk perception—the way a population understands the hazards it may be exposed to, its vulnerability related to that hazard, and the probability of a hazard occurring—may require a qualitative study to determine how a population is likely to prepare for and react to such an event. For instance, using a mental model with respondents affected by flooding, researchers from Carnegie-Mellon University found that most knew very little about the direct causes of flooding and how to protect themselves, and they perceived mitigative efforts such as flood insurance to be unwarranted despite a government effort to address those issues.⁸ Such methods provide the ability to get at the underlying thought processes of an at-risk population. Qualitative techniques bring other disciplines into the discourse, such as anthropology, sociology, communications, and social sciences, thus enabling researchers to gain insight into how and why things work in a population and to improve the ability of the population to address its own problems.

Vulnerability analyses can draw from “lessons learned”-type studies in the postdisaster phase. A cohort study of the deaths following the Taiwan earthquake of 1999 showed that people with mental disorders, moderate physical disabilities, or recent hospitalization were the most vulnerable.⁹ Similarly, women and elderly groups were found to be at higher risk of injury during the 1994 earthquake in Northridge, California. Those who lived in mobile homes during the 1978 Wichita Falls, Texas, tornado had a significantly higher risk of injury or death.¹⁰ In populations at high risk for a given hazard, applied quantitative epidemiology can identify vulnerable groups for targeted interventions before the next disaster.

Rapid Assessments and Needs Evaluations

The cornerstone of epidemiology's role in disasters is during the response itself. The epidemiologic methods of rapid assessments, surveys, and surveillance should parallel the emergency response. The outcome measures of these methods are termed *indicators*—the quantitative or qualitative criteria used to correlate or predict the value or measure of a program, system, or organization—tools used to inform and guide decision-making during the crisis and beyond.¹¹ A few examples of general indicators are listed in Box 51-1.

BOX 51-1 COMMON INDICATORS IN RAPID ASSESSMENT

Demographics

- Vulnerable group identification

Health

- Morbidity and mortality rates
 - Crude mortality
 - Under-5 mortality
 - Cause-specific attack
 - Diarrheal illness
 - Acute respiratory infection
 - Malaria (in non-immune)
 - Measles
- Measles immunization coverage

Nutrition

- Global acute malnutrition ($-2 z$ score weight for height)
- Macronutrient intake
 - Energy (kcal/day)
 - Protein (% of total energy)

Food Security

- Household access

Water and Sanitation

- Quantity (liters/person/day)
- Quality (fecal coliforms/100 ml)
- Household access
 - Distance to source
 - Source/population

Shelter

- Area per person
- Fuel availability (kg/household/day)

Rapid assessments answer the primary questions of “what has happened” and “what is needed”?¹² In the chaos of the moment, multiple agencies will be attempting to get solid information for decision-making and coordination, and information sharing among various agencies will be critical. Often these assessments out of necessity will be “quick and dirty,” depending on the nature and timing of the disaster and the need to have information readily available. More important is for public health providers with expertise in field epidemiology to be able to use the right type of epidemiologic tool for the right information. A variety of sources from a variety of methods will allow for the triangulation of data, where multiple sources of information can lend verification to each other—a “cross-checking” reference point. Bradt and Drummond¹³ propose an assessment tool containing a “minimum essential data set” of health information that will be uniformly understood and used by all stakeholders partially or entirely. Similar assessment indicators can be found in a number of field-tested resources (Box 51-2).

Rapid assessments are used to examine the situation and the needs, ideally within the first several days of the impact. In so doing, public health providers determine the magnitude of the emergency by characterizing and quantifying the affected population; they identify existing and potential public health problems; they measure present and potential impact, especially health and nutritional needs; they assess resources needed, including availability and capacity of a local response; they aid in planning and guiding an appropriate external or international response; they identify vulnerable groups; and they provide baseline data from which the public health system can be restored.¹⁴ Often it is the *indirect* effects of a disaster, the subsequent migration of populations, separation from food supplies, and destruction of public health infrastructure that eventually cause the greatest mortality and morbidity. After the Asian tsunami of December 26, 2004, a rapid assessment in the six affected provinces of Thailand identified a 1.7 times greater increase in the incidence of diarrheal illness and a significant increase in wound infections compared with normal.¹⁵ Because Hurricane Charley in August 2004 devastated several counties on Florida’s Gulf Coast having a large concentration of older adults, the U.S. Centers for Disease

Control and Prevention (CDC) and Florida Department of Health performed a rapid assessment of households with adults over 60 years of age who were found to have disruption in medical care for chronic medical conditions.¹⁶

Rapid assessments and their interpretations critically depend on reliable population denominators. The *count* refers to the absolute number of a population in a specific area in a specific period of time. First-world countries will have background demographic statistics of the population before the disaster strikes, but less developed places or areas with migrating populations may have inexact or nonexistent numbers. Global sources such as the World Health Organization, CRED, Epicentre, or the CDC are sources of information and publications that include *baseline data* on endemic diseases, baseline mortality rates, morbidity incidence rates, nutritional status, sources of healthcare, and the level of health service disruption by past disasters (Table 51-1). Other non-health sources of population data include the U.S. Central Intelligence Agency (CIA)’s *World Factbook*, which provides individual country profiles on infrastructure and government, maps, and census data.

In almost all cases, an effort at population reconnaissance must be made to determine the numbers of affected persons relative to the entire population. Fly overs using aerial photography, satellite images linked to geographic information systems, mapping strategies, or drive- or walk-throughs using handheld global positioning system receivers are typically done to get a rough idea of absolute numbers and degree of devastation. Using multiple approaches allows for the triangulation of population numbers.

Denominators are necessary to calculate a *rate*, the frequency of an event (usually morbidity or mortality) in a population in a specific period of time. Crude rates are calculated for an entire population, whereas specific rates are computed for a specific subgroup of the population. Specific rates highlight vulnerable groups and may be age specific, sex specific, occupation specific, and so on. Death rates are one of the most sensitive indicators of the success (or failure) of emergency relief efforts. Crude mortality rates (CMR), also known as crude death rates (CDR), reflect deaths within a population over a period of time:

$$CMR = \frac{\text{Number of deaths in time period}}{\text{Total population at mid-period}} \times \frac{K}{\text{Number of days in time period}}$$

where K is a uniform constant by which rates or proportions can be multiplied for purposes of comparison and easy understanding—usually a multiple of 10 (such as 1000, 10,000, or 100,000). CMRs are usually expressed during the emergency phase in deaths per *10,000* population per *day*. CDRs are employed after the health crisis of the impact has passed and are expressed as deaths per *1000* population per *year*. For either figure, the formula for calculation is the same and the underlying rate does not differ.

The consensus among humanitarian agencies is that successful humanitarian relief programs should aim for a

CMR at or below twice the population’s baseline (pre-disaster) CMR. A doubling of the baseline rate defines a humanitarian disaster and immediate response. The average baseline CMR in the least developed countries is 0.38 deaths/10,000 persons/day; in developed countries it is 0.25 deaths/10,000 persons/day.¹⁷ A robust system of recording births and deaths as well as a registration system for displaced populations are needed for accurate denominators. This baseline will serve as the foundation by which agencies and disaster managers can follow the trends of mortality and morbidity over time, the function of a surveillance system (see Chapter 37).

Age- and sex-specific death rates—the under-age-5 mortality rate (U5MR) is a frequently used example—are used in emergencies to identify subgroups particularly at risk during the disaster and to further clarify the information buried in the CMR figures. Because young children are a vulnerable group in a disaster, a rise in death rates among children younger than 5 years of age is a warning indicator of significant public health disturbance. Similar to the CMR calculation, the U5MR uses the number of deaths in children younger than 60 months of age over a time interval divided by the total population of children younger than 5 years at the middle of that time period:

$$USMR = \frac{\text{Number of U.S. deaths in time period}}{\text{Total U.S. population at mid-period}} \times \frac{K}{\text{Number of days in time period}}$$

This is expressed in terms of under 5 deaths per 10,000 population per day (during the emergency phase) or per 1000 population per month (in the post-emergency phase). U5MR and CMR are the most commonly used mortality indicators during a disaster.

The causes of specific mortality rates can identify the common causes of death during the emergency. Aside from the mortal injury caused by the disaster itself, the developing world often suffers mortality from diarrheal diseases, measles, acute respiratory infections, malnutrition, and malaria. To be rapid and efficient while maintaining accuracy, uniform simple case definitions (as opposed to laboratory confirmations) should be used in such settings to classify cases. Cases classified by standard case definitions are the numerator with the other components of the formula similar to the previous mortality rate calculations:

$$\text{Cause-specific MR} = \frac{\text{Number of deaths from specific cause in time period}}{\text{Total population at mid-period}} \times \frac{K}{\text{Number of days in time period}}$$

Cause-specific mortality rates can target interventions: if the incidence of deaths from diarrheal illness is high, then a focus on water, sanitation, and hygiene will be most important.

Various causes of injury morbidity vary according to the disaster type. However, infectious diseases are common in all disasters that disrupt the public health infrastructure. The five diseases mentioned above, along with meningitis, should not be missed during a rapid assessment. Interviewing health workers, reviewing clinic records, or directly observing households are techniques to determine the incidence and prevalence of a disease. *Incidence* refers to the number of new cases of a disease that occur during a specific time period; *prevalence* is the number of cases present in the population at the time of assessment.¹⁸ As the emergency phase passes into the postemergency phase, secondary wound infections, acute exacerbations of chronic diseases, and men-

tal health issues add to the burden of the disease in the disaster-affected population.

Participatory Appraisals

In an effort to enhance the role of the affected population in the decision-making process during the response and reconstruction, researchers use participatory methods. Typically these are qualitative unstructured interviews with key informants, persons specifically selected because of their unique role in the community. Such respondents provide insight into the dynamic of the affected community or group, its interpretation of its environment, level of migration, needs, behaviors, and attitudes. Mental health issues require this kind of participatory ethnographic approach. Assessment teams take a listener/observer role. Relatively simple, inexpensive, and fast, participatory appraisals provide subjective nongeneralizable data that often require alternative methods for confirmation. Group interviews can generate “problem trees,” a participatory exercise that identifies problems and their root causes.

Surveys: In-Depth Sectoral Assessments

A survey involves a more in-depth study compared with a rapid assessment, usually by means of a detailed study design that employs a sampling methodology and relies on observations, interviews, or questionnaires to yield data on a specific aspect of the disaster. That data undergoes a formal analysis and interpretation. Surveys are used for “one-off” assessments of a given sector (e.g., shelter), subpopulation (e.g., children younger than 5 years), or public health problem (e.g., acute malnutrition). In general, a survey should be used when greater precision is needed to make informed decisions.

Nutritional surveys are the common example. Since undernutrition rates are associated with *excess mortality* from complications of preventable illnesses such as diarrhea, measles, malaria, and acute respiratory infections, it is imperative to determine the level of acute malnutrition within the disaster-affected population. The severity of acute malnutrition in young children is expressed as a *z* score—that difference between the weight-for-height ratio for an individual child and the median value of the population of children divided by the standard deviation of the population. The measure of greatest interest is that segment of the population below $-2 z$ score termed *global acute malnutrition*, or *wasting*. Finding the prevalence of wasting within the population of children requires the systematic measuring of weight and height—in essence, a probability sample.

A *sample* is that subset of a population that represents the population well enough to make inferences about it. A sample may be one of two types: a probability sample or nonprobability sample. The former uses random selection to minimize inherent bias, ensuring that each person within the population has an equal chance of being selected; the latter implies that samples are chosen subjectively by the researcher. Nonprobability sampling is quick and easy because it does not require a full listing of the population. If a public health worker wanted to know the prevalence of crush injury after an earthquake

to determine the amount of supplies needed, he could visit clinics. However, this nonprobability sample would miss those in the population who still may suffer crush injury but could not make it to a health facility. Thus, nonprobability sampling makes it difficult to measure the level of uncertainty of the results. More often, a probability sample complete with a sampling frame is needed to answer the research question appropriately. *Sampling frames* are full listings of the population as persons or households arranged in units of analysis. Invariably such sample surveys are more expensive (and may be prohibitive in the setting of low resources), demand time (when often an answer is needed immediately), and require a certain level of training (often not found in developing countries).

In addition to nutritional indicators, surveys are commonly used in disasters to measure level of food security, immunization coverage, prevalence of mental health problems, access to clean water, household use of water, hygiene practices, level of infrastructure damage, shelter density, and livelihood disruption, among many other areas of interest. Because they require expertise, planning, and time, surveys are done on any given area of interest usually as a “one-off” event, a snapshot in the disaster response continuum. To adequately follow indicators of interest in real time, a more flexible, rapid, and simple tool should be used.

Surveillance

Monitoring the mortality and morbidity indicators mentioned above, observing for epidemic outbreaks, and monitoring trends in endemic diseases is the role of surveillance in the emergency phase. As the disaster response transitions from the emergency phase to the postemergency and rehabilitation phases, trends in key indicators will measure the effectiveness of the relief efforts. The role of a surveillance system and its applications are discussed in Chapter 37.

PITFALLS

Each epidemiologic method has its drawbacks. Vulnerability analyses fail when they don't take into account all the factors that contribute to the structure of the human environment, particularly the knowledge, attitudes, and behaviors of the population at risk. Rapid needs assessments continue to suffer from lack of common shared indicators between donor agencies, NGOs, and international organizations. Mortality rates may be inappropriately inflated or deflated if the population estimates are not accurate. Respondents may easily introduce biases in participatory appraisals, for example, exaggerating the needs of the community knowing that the interviewer will likely have access to outside resources or, because of mistrust or pride, will minimize the needs. Bias is also inherent in nonprobability sample surveys; critical errors can result when such samples are generalized to a population. Since the humanitarian response depends on each of these methods, it is critical that they are used correctly and appropriately.

Measures of Effectiveness in Disaster Management

Frederick M. Burkle, Jr. and P. Gregg Greenough

Measures of effectiveness (MOEs) are operationally quantifiable management tools that provide a means for measuring effectiveness, outcome, and performance (including success or failure) of disaster management.^{1,2} The foundation units or elements for developing MOEs are found in indicators used to assess, monitor, and evaluate services provided by disaster relief agencies and organizations.³ Most importantly, MOEs have the capability to serve as an integration performance tool that speaks to the disaster timeline or critical pathway and allows for the horizontal crossing of sector and professional boundaries that may influence both policy decisions and the operationalizing of policy.⁴

HISTORICAL PERSPECTIVE

MOEs were first used in industry to measure the performance of products.² Disaster research and application of MOEs were directed primarily toward disaster sector-specific indicators, such as mortality rates, under-age-5 mortality rates, case fatality rates, and water requirements per person per day, to name but a few.¹ Eventually, multiple indicators were studied to determine the influence of multiagency and multisectoral indicators on overall performance. For example, in Somalia, the military developed over 500 security-related indicators, only a small number of which actually were essential to assessing the success or failure of security on the mission. By applying these security indicators against other humanitarian indicators used by relief agencies and logisticians, a clearer picture was gained as to what might be contributing to or detracting from the performance of the mission. For example, failures to adequately mitigate malnutrition in some geographic sectors were found by MOE analysis to be more related to lack of security and access to aid for the intended recipients of care rather than lack of supplies delivered to the local warehouses.²

CURRENT PRACTICE

Currently, MOEs are used as combined “essential indicators” to gain an overview of management performance and

to help define critical pathways (e.g., the multisectoral/agency organizational response), to assess performance, and to define the end state or sustainability of operations. Essential indicators are MOEs as they subsume the essential indicators, often from each sector, into a definable horizontal measure of overall disaster management. As such, they are the quantifiable language of a critical pathway that disaster managers follow, initially on an hourly and subsequently daily basis, to ensure that management requirements are being met.³ If expected requirements are not met across the management timeline, this becomes a *negative variance* that must be investigated as to the cause and solved as soon as possible. Also, there may be an unexpected improvement or acceleration of the disaster response timeline that becomes a *positive variance*, which may eventually alter the way the timeline process of management will be defined in future disasters.

Most critical is that MOEs have the capability to unify the language of the disaster event, thereby bringing together the strange bedfellows made up of the varied disaster response agencies and organizations. If disaster organizations agree to share information and work for a common goal, MOEs are a priority in management, evaluation, and monitoring for all concerned, especially the beneficiaries of relief and development.

Whereas MOEs must be quantifiable in nature, this does not exclude semiquantitative or -qualitative indicators that often successfully provide a reliable measure of social, cultural, behavioral, and mental health disaster-related services. To be useful, indicators and the MOEs they support must be defined as precisely as possible, easily understood, reliable, valid, simple, and informative. MOEs must be consistently measurable, cost-effective, sensitive, timely, mission related, and appropriate to the developed critical pathway followed by disaster managers. The key to understanding MOEs and the process by which they are generated lies in (1) the recognition of which indicators are considered essential measures of sector performance; (2) the assessment of the applicability and reliability of these essential indicators and whether they meet usefulness criteria; and lastly (3) the ability of these essential indicators to provide the coordinating language of the timeline or critical pathway specific to the disaster event (Fig. 52-1).

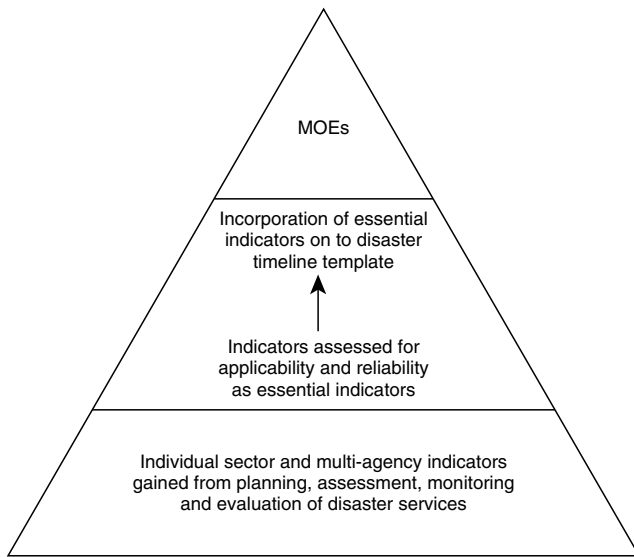

FIGURE 52-1 Measures of effectiveness are based on essential indicators.

MOEs have been applied to complex humanitarian emergencies to study complex multiagency performance as well as in narrowing the field of multiple available indicators in a large-scale bioterrorism event to a workable number of essential indicators that will readily weather management success.^{1,2,5} Here the essential indicators that make up the operational MOEs include:

- Measuring response capacity of deployed biologic sensor devices linked to a real-time public health surveillance system;
- Measuring how rapidly a full-coverage health information system is mobilized with timely dissemination of accurate information;
- Measuring variance compliance to a bioagent-specific management timeline;
- Measuring decline in mortality and morbidity;
- Measuring control of transmission rate (R_0) in communicable outbreaks; and
- Measuring management resource distribution across the entire cohort of a vulnerable population.

In this regard, indicators for education of suspected or exposed victims may indeed be useful but may contribute more critically to the knowledge base of more essential indicators such as health information system and decline in mortality and morbidity. If mortality and morbidity is not declining as expected, then the contributing indicators are analyzed for cause.

PITFALLS

The main pitfalls of MOEs are organizational ones. In the heat of a disaster event, they are often neglected or forgotten. It takes some agency leadership to organize a multiagency effort, and although the United Nations (UN) includes MOEs as a need in peacekeeping missions, this is often left to the discretion of the mission commander. That said, the after-action report for UNPROFOR, the UN mission to the Former Yugoslavia, criticized the lack of MOEs in the mission planning. The inherent verticality of agencies and organizations in disasters prohibits the horizontal cooperation needed to get MOEs operational. Timelines or critical pathways, although available for natural and chemical disasters management, have not been developed for complex emergencies and large-scale bioterrorism events, the two disasters where they are most needed.

chapter 53

Lessons Learned as a Result of Terrorist Attacks*

Mark E. Keim

The threat of terrorism is a high-priority national security and law enforcement concern in the United States. Modern policy on combating terrorism against the United States has been evolving over the past 30 years. A series of presidential decision directives, implemented guidance, executive orders, interagency agreements, and legislation now provide the basis for counterterrorism programs and activities in more than 40 federal agencies, bureaus, and offices.

Unfortunately, societal reactions and public policy regarding disasters do not always translate into effective outcomes of “lessons learned.” Traditionally, after-action studies and reports have been composed of largely anecdotal observations offered by relatively small consensus groups. Although helpful, these methods frequently lack scientific validity. Since most responders (and political policy makers) do not experience a statistically significant number of disaster events themselves, so-called lessons learned often represent the same redundant themes and epiphanies of a relatively novice cohort. In one 2-year comparative study of catastrophes in disaster-prone India, many of the same problems listed as “lessons learned” from one national disaster were only to be repeated just 2 years later and, ironically, were again listed as *lessons learned* in yet another after-action report (Giannone P, personal correspondence, 2004). As another example, remarkable parallels may also be drawn between lessons learned at the Pan American Health Organization Meeting on Evaluation of Preparedness and Response to Hurricanes Georges and Mitch (held over a decade ago)¹ and recent U.S. Government Accountability Office (GAO) reports involving federal and state efforts related to terrorism preparedness.²⁻⁵

Unfortunately, it has also been the case that even when sound findings are identified within an after-action review, these lessons are “learned” by the group but not implemented into an effective policy. New policies may even become implemented but never validated by real-world experience. And finally, even the best-validated

public policies may not be maintained in the absence of an ongoing risk-reduction program.

Terrorism itself has been an age-old threat to the public health and security of many populations throughout the world. During the past three decades, terrorist attacks against the United States have led to a significant number of legislative, regulatory, organizational, and programmatic actions associated with very comprehensive and ambitious expectations. More study is needed before we can conclude to what extent these major changes will have a lasting and significant impact on capacity and capability to deal with future disasters or the practice of disaster medicine as a health science.

Even though the extent of long-term impact remains uncertain, two major accomplishments have become realized: (1) national capacity of emergency management appears to have been increased, and (2) awareness and possibly even commitment to the issue of emergency preparedness also appear to be greater.⁶ It would appear that the information and knowledge about what to do in response to the terrorist threat already existed before September 11, 2001. What was lacking was the political backing for change and the political will to act. A rapid series of events involving emergency management and protection of critical infrastructure then followed.

This chapter identifies recent terrorist events that have had a significant impact upon U.S. society and public policy. The discussion correlates these policies with widely accepted doctrines of incident management and disaster risk reduction. From this perspective, these lessons learned represent a recent trend for implementation of what may be more accurately described as already well-established doctrines of disaster medicine and emergency management.

HISTORICAL PERSPECTIVE

Development of Modern U.S. Emergency Management Policy

Modern emergency management policy in the United States began with the “Unlimited National Emergency”

*The material in this chapter reflects solely the views of the authors. It does not necessarily reflect the policies or recommendations of the Centers for Disease Control and Prevention or the U.S. Department of Health and Human Services.

(Proclamation 2487 of May 27, 1941) immediately before World War II. Over three decades later, out of concern for a catastrophic earthquake predicted to occur in the central United States, the Earthquake Hazards Reduction Act of 1977 mandated the development of a Federal Response Plan for a Catastrophic Earthquake. In July 1979, Executive Order 12148 delegated authority to the U.S. Federal Emergency Management Agency (FEMA) to establish federal policies and to coordinate all civil defense and civil emergency planning, management, mitigation, and assistance functions of executive agencies. At this time, FEMA was also assigned the lead responsibility for response to consequences of terrorism. The Robert T. Stafford Disaster Relief Act PL 100-707 was enacted in 1986 to formalize a coordinated federal policy. In 1990, FEMA issued the Federal Response Plan to establish a process for coordinated delivery of federal disaster assistance. After significant criticism of the response to Hurricane Andrew in 1992, Congress adopted a formal *all-hazards approach* to emergency management in the National Defense Authorization Act of 1994, PL 103-160.

In June 1995, President Clinton issued Presidential Decision Directive 39 (PDD 39), the central blueprint for the U.S. counter-terrorism strategy. PDD 39 elaborated a strategy for combating terrorism consisting of three main elements: (1) reduce vulnerabilities and prevent and deter terrorist acts before they occur, (2) respond to terrorist acts that do occur, including managing crises and apprehending and punishing terrorist perpetrators, and (3) manage the consequences of terrorist attacks. All three elements of the strategy include terrorism involving weapons of mass destruction.⁷ Emergency managers will recognize these elements as phases of the risk reduction cycle including disaster prevention, mitigation, and response.

The Defense Against Weapons of Mass Destruction Act of 1996, Public Law 104-201, September 23, 1996 (also known as the Nunn-Lugar-Domenici Act), drew on the convergence of federal assets at the Atlanta 1996 Olympic Science and Technology Center^{8,9} and directed this momentum to set in place a long-term effort to prepare domestic response for terrorist threats.

Development of Incident Management Systems

The Incident Command System (ICS) was conceptualized more than 30 years ago, in response to a devastating wildfire in California. As a result, Congress mandated that the U.S. Forest Service design a system that would improve wildland fire protection agencies to effectively coordinate interagency action and allocate suppression resources in dynamic situations. This system became known as FIRESCOPE (FIrefighting REsources of California Organized for Potential Emergencies) ICS. Although FIRESCOPE ICS was originally developed to assist in the response to wildland fires, it was quickly recognized as a system that could help public safety responders provide effective and coordinated incident management for a wide range of situations, including

floods, hazardous materials accidents, earthquakes, and aircraft crashes. In 1982, all FIRESCOPE ICS documentation was revised and adopted as the National Interagency Incident Management System (NIIMS). In Homeland Security Presidential Directive-5 (HSPD-5), President Bush called on the Secretary of Homeland Security to develop an NIMS to provide “a consistent nationwide approach for federal, state, tribal, and local governments to work together to prepare for, prevent, respond to and recover from domestic incidents,” regardless of cause, size, or complexity.¹⁰

On March 1, 2004, after close collaboration with state and local government officials and representatives from a wide range of public safety organizations, Homeland Security issued the NIMS guidelines.¹⁰ These incorporate many existing best practices into a comprehensive national approach to domestic incident management and are applicable at all jurisdictional levels and across all functional disciplines or public sectors.

Development of Disaster Risk Reduction Strategies

In 1994, the States Members of the United Nations, having met at the World Conference on Natural Disaster Reduction in the city of Yokohama, Japan, in partnership with nongovernmental organizations and with the participation of international organizations, the scientific community, business, industry, and the media affirmed that “Disaster prevention, mitigation, and preparedness are better than disaster response in achieving the goals and objectives of the Decade. *Disaster response alone is not sufficient, as it yields only temporary results at a very high cost.* We have followed this limited approach for too long. This has been further demonstrated by the recent focus on response to complex emergencies, which, although compelling, should not divert from pursuing a comprehensive approach. *Prevention contributes to lasting improvement in safety and is essential to integrated disaster management*” [emphasis added].¹¹

Development of Disaster Medicine

During the late 1980s, disaster medicine began to develop in the United States as a subspecialty of emergency medicine.^{12,13} In the 1990s, several disaster medicine fellowships were established and graduated at least six disaster medicine subspecialists. None of these programs received earmarks for federal or state support of disaster medicine. All were closed by the end of the decade.

Recent Terrorist Events That Have Influenced U.S. Policy

The development of new disaster policy is dependent on a society’s perception of risk. Public perception of risk is known to be higher immediately after the occurrence of a major disaster. During this time there is a notable window of opportunity for change in disaster-reduction policy. Table 53-1 is a listing of recent terrorist events and their corresponding influence on resultant U.S. policy.

TABLE 53-1 RECENT TERRORIST EVENTS THAT HAVE INFLUENCED U.S. POLICY

DATE	EVENT	DESCRIPTION	SIGNIFICANCE
1984	Bhagwan Rajneesh Salmonella Release	<ul style="list-style-type: none"> Salmonella bacteria released in 10 Dalles, Oregon, restaurants Outbreak linked to Bhagwan Rajneesh religious cult years later 	<ul style="list-style-type: none"> This was the first large-scale biologic attack in the United States with a high morbidity rate. For years, this outbreak went largely unrecognized as an intentional event.
1988	Bombing of Pan Am Flight 103	<ul style="list-style-type: none"> No deaths, over 800 infected Parcel bomb detonated on plane while en route from London to New York, explodes over Lockerbie, Scotland Linked to Libyan Militant Islamic Extremist (MIE) terrorist cell Killed 270 	<ul style="list-style-type: none"> In 1989, President George H. W. Bush issued Executive Order 12686, which formed the Presidential Commission on Aviation Security and Terrorism. President George H.W. Bush signed the Aviation Security Improvement Act of 1990.
1993	World Trade Center (WTC) Bombing	<ul style="list-style-type: none"> Truck bomb detonated in the WTC parking garage Linked to MIE including multiple Arab nationalities. 	<ul style="list-style-type: none"> Congress enacted the "National Defense Authorization Act for Fiscal Year 1995, which directed FEMA to: <ol style="list-style-type: none"> Prepare federal response plans and programs for the emergency preparedness of the United States; and Sponsor and direct such plans and programs to coordinate such plans and programs with state efforts. <ul style="list-style-type: none"> This was the first time that a nonstate group used a chemical weapon against civilians Demonstrated how terrorist groups could recruit scientists, obtain deadly chemical or biologic agents, and put plans into action.
1994-1995	Aum Shinrikyo Sarin Attacks	<ul style="list-style-type: none"> Killed 6, wounded 1042 1994: Japanese religious cult, Aum Shinrikyo, released sarin nerve agent in a residential area of Matsumoto, Japan. This event killed 7 and injured 500. 1995: Same group released sarin in the Tokyo subways, killing 12 and injuring hundreds. 	<ul style="list-style-type: none"> The 1996 Nunn-Lugar-Domenici Act (a.k.a., Defense Against Weapons of Mass Destruction [WMD] Act of 1996) was passed. In 1997, the Terrorist Annex to the Federal Response Plan was adopted by FEMA. These events provided evidence of extensively coordinated planning and execution. This was the first instance of large-scale bombing caused by U.S. domestic terrorists This was the first use of the President's authority under the Stafford Act to "self-initiate" an emergency declaration for emergencies with federal involvement. Experts other than foreign policy and security specialists became more involved in terrorist preparedness and response (most notably, disaster medicine) This event initiated increased awareness of occupational health concerns among disaster responders First credible threat for use of an RDD (a.k.a. "dirty bomb") by a sub-national group.
1995	Bombing of the Murray Federal Building in Oklahoma City	<ul style="list-style-type: none"> Truck bomb detonated near the Alfred P. Murray Federal Building in Oklahoma City, Oklahoma. Linked to U.S. right-wing extremists Killed 169, injured more than 500 	<ul style="list-style-type: none"> This event was an asymmetric attack on U.S. military facility by MIE. This was an asymmetric attack on U.S. military facility by MIE.
1995	Chechnyan Threaten to Use Radiologic Dispersion Device (RDD) Bombing of Lebanon Marine Barracks Bombing of Khobar Towers	<ul style="list-style-type: none"> Chechnyan separatists direct news reporter to Moscow park where cesium-137 RDD weapon is found Truck bomb detonated near U.S. military barracks in Lebanon Linked to MIE Truck bomb detonated near U.S. military barracks in Dhahran, Saudi Arabia Linked to MIE Killed 19 Americans, injured 500 	<ul style="list-style-type: none"> There was an unprecedented state and federal preparedness activities related to the 1996 Olympic games. In 1997, the White House Commission on Aviation Safety and Security (Gore Commission) issued a report recommending that "The federal government should consider aviation security as a national security issue and provide substantial funding for capital improvements." The Department of Homeland Security 2005 budget includes \$61 million for the research and development of countermeasures to protect commercial aircraft from shoulder-fired, surface-to-air missiles.
1996	Crash of TWA Flight	<ul style="list-style-type: none"> Explosion of airliner during takeoff in New York. Initially believed to be result of a terrorist attack using surface-to-air missile Later ruled to be accidental 	

(Continued)

TABLE 53-1 RECENT TERRORIST EVENTS THAT HAVE INFLUENCED U.S. POLICY—Cont'd

DATE	EVENT	DESCRIPTION	SIGNIFICANCE
1996	Bombing of Atlanta Olympic Games	<ul style="list-style-type: none"> Occurred within days of the start of the 1996 Olympics Shoulder-fired surface-to-air missiles were used by MIE to attack aircraft in Kenya, Saudi Arabia, and Iraq during 2003-2004 Pipe bomb explodes at Centennial Olympic Park, in Atlanta, Georgia, during the ninth day of the 1996 Summer Olympics 	<ul style="list-style-type: none"> This bombing occurred during first interagency coordination of federal WMD response teams. Title XIV of the Defense Authorization Act of 1996, The Defense Against WMD Act (a.k.a. Nunn-Lugar-Domenici Act) was adopted. The Terrorist Annex to the Federal Response Plan was adopted by FEMA.
1998	U.S. Embassy Bombings in Kenya and Tanzania	<ul style="list-style-type: none"> Killed one, injured 112 Truck bombs detonated simultaneously near U.S. embassies in Nairobi and Dar es Salaam Linked to MIE, Al-Qaeda terrorist network 	<ul style="list-style-type: none"> The first forward staging of a medical stockpile in preparation for WMD casualties was created. This was the first large-scale attack on U.S. embassies or consulates caused by MIE terrorists. The event provided evidence of extensively coordinated planning and execution. The United States responded with cruise missile strikes in Afghanistan and Sudan. U.S. policy shifted focus toward proactive and global policy that is less constrained about targeting terrorists, their bases, and their infrastructure.
2000	Attack of the U.S.S. Cole	<ul style="list-style-type: none"> Killed 280, injured over 5000 Explosion occurred on the destroyer U.S.S. Cole docked at the harbor in Aden, Yemen Linked to MIE, Al-Qaeda terrorist network 	<ul style="list-style-type: none"> First HHS public health and medical response to overseas terrorism This was the first asymmetric attack on a U.S. naval warship perpetrated by MIE. The Department of Defense subordinated its terrorism analysis capability under the Joint Chief of Staff/Intelligence. This reduced confusion and clarified responsibility for warning.
2001	WTC and Pentagon Attacks	<ul style="list-style-type: none"> Killed 17, injured 39 Hijacked airliners deliberately flown into WTC towers in New York City and the Pentagon in Washington, DC Linked to MIE, Al-Qaeda terrorist network Killed over 3000, injured hundreds 	<ul style="list-style-type: none"> This attack has had a significant long-term economic impact as well as symbolic significance. U.S. response included at least 10 pieces of national legislation, two Executive Orders, one Homeland Security Decision Directive, one new federal department (i.e., Department of Homeland Security), and several significant reports. There was unprecedented speed in the passage of major federal legislation, in absence of Congressional hearings or task forces. A major reorganization of U.S. intelligence organizational structure occurred in 2004 consistent with recommendations of the 9/11 Commission report.
2001	Anthrax Letter Attacks	<ul style="list-style-type: none"> Letters containing anthrax spores mailed to news media personnel and Congress Leads to the first cases of intentional anthrax infection in the United States Infections follow a 3-year history of over 1500 anthrax letter hoaxes. Perpetrators remain at large Killed 5, infected 18 	<ul style="list-style-type: none"> This event was the second-largest-scale biologic attack in the United States and had the highest mortality rate. Reports cited speculation regarding U.S. domestic origin of terrorism. The challenges and shortcomings facing the nation's public health system were revealed. The Federal Concept of Operations Plan (CONPLAN) for responses to terrorist attacks was not used. The FBI did not exercise its crisis management authority, nor did FEMA exercise consequence management authority as called for by PDD 39. The Federal Response Plan was never activated.
2002-2004	Bombings and attacks in Russia, Indonesia, Philippines, Kenya, Saudi Arabia, Afghanistan, Iraq, and Spain	<ul style="list-style-type: none"> A series of terrorist bombings and attacks involving numerous nations Most attacks are linked to MIEs and some to national separatist movements Most events kill a few to several hundred victims 	<ul style="list-style-type: none"> These events illustrated MIE tactics for attacks against broader pro-Western interests. Events related to national separatist movements revealed a growing level of sophistication in coordination and execution of attacks. Nations other than the United States became frequent targets.
2004	Attack on US Consulate in Jeddah, Saudi Arabia	<ul style="list-style-type: none"> A car bomb detonation and subsequent small arms attack of the US consulate in Jeddah, Saudi Arabia. Linked to MIE, possibly Al-Qaeda 	<ul style="list-style-type: none"> Recent U.S. activities resulting in hardening and increasing security of U.S. embassies and consulates proved valuable in mitigating the impact of the attack

CURRENT PRACTICE AND LESSONS LEARNED

Lessons learned as result of recent terrorist attacks can be divided into two main categories: those involving a trend toward a more comprehensive disaster risk reduction strategy (Table 53-2), and those building capacity for more effective models of incident management (Table 53-3).

PITFALLS

Homeland Security and Emergency Management Remain Poorly Defined

Although a new homeland security emphasis is under way throughout the federal government, the process is still evolving. Additional actions to clarify missions and activities will be necessary, and some agencies will need to determine how best to support both homeland security and nonhomeland security missions.¹⁴ Many people are not clear on just what homeland security is and how it is in fact quite different from all-hazard emergency management. People tend to use the terms *homeland security* and *emergency management* synonymously.

The extent to which the homeland security mission is displacing the natural and technologic disaster function is also an important question. Related to this question is the degree to which extensive experience in natural hazards has been leveraged (or ignored) in the new reality of homeland security.

The Need for an All-Hazard Strategic Approach and National Strategy

According to WL Waugh in 2000, "For the most part, policies and programs have been instituted and implemented in the aftermath of a disaster, based almost solely on that disaster experience, and with little investment in capacity building to deal with the next disaster."¹⁵

After the events of September 11, 2001, national legislation was enacted and organizational changes occurred in the absence of any hearings or studies being ordered to determine what went wrong and what remedies were needed. Another unusual characteristic of the aftermath of this disaster was the speed with which the major federal organizational and coordination changes occurred, even before Congressional hearing or special task forces were formed.¹⁶

Because the drafters of Public Health Security and Bioterrorism Preparedness Act (June 12, 2002), Public Law 107-188, "did not have detailed information as to how other federal response plans operated or were designed to operate, the statute tends to encourage stove-piping of information, planning and response by the medical community." Additionally, the principal assets of the medical community, including personnel and institutions, are private; therefore, statutory mandates are difficult to apply.¹⁶

The first step toward disaster risk reduction involves adopting a strategic national approach. The first annual Gilmore report (REF) to the President and the Congress of the Advisory Panel explored a broad range of issues regarding weapons of mass destruction and details of actual terrorist attacks. The report formulated several initial policy recommendations, one of which included "the need for a national strategy to address domestic response to terrorism."¹⁷ The second annual Gilmore report re-sounded the alarm in 2000, stating, "The United States needs a functional, coherent national strategy for domestic preparedness against terrorism."¹⁸

Comprehensive disaster risk-reduction measures include prevention, mitigation, response, and recovery phases. Recent terrorist attacks have driven emergency management policy toward prevention, preparedness, and mitigation as the most cost-effective interventions. However, these three pre-event disaster risk-reduction activities and programs remain underdeveloped for natural disasters in the United States.

The Need for National Threat and All-Hazard Risk Assessment

According to a Government Accountability Office report in 2001, "The first step toward developing a national strategy is to conduct a national threat and risk assessment."² By 1999, a national-level risk assessment of potential chemical and biologic terrorist incidents had not yet been performed.¹⁹

A *risk assessment* is a decision-making process that is used to estimate risk and then to establish requirements and priorities. The components of risk assessment include asset and loss impact assessment, threat assessment, and vulnerability analysis.²⁰ Comprehensive risk management strategies involve risk assessment, cost-benefit analysis, risk communication, and risk-reduction activities.

The Department of Justice and the Federal Bureau of Investigation (FBI) have collaborated on such an assessment, but as of September 2001, they had not formally coordinated with other departments and agencies on this task.²

Many conflicting statements have been made in public testimony before Congress and in the press concerning the risk of dissemination of a chemical or biologic agent on U.S. soil.⁶ The Centers for Disease Control and Prevention (CDC), in partnership with other military and civilian federal governmental organizations, has developed a list of priority agents for biologic warfare.²¹ The intelligence community has recently produced National Intelligence Estimates and other high-level analyses of the foreign-origin terrorist threat that include judgments about the more likely chemical and biologic agents that would be used.

In the Homeland Security Act of 2002, Congress required the Homeland Security Department to implement a system for analyzing information on terrorist threats. The Terrorism Threat Integration Center was announced in February 2003 and is housed within the Central Intelligence Agency, serving as a central repository for all government intelligence information. However, this repository does not integrate significant

information regarding natural and technologic disaster hazards, other than terrorism.

The Need for Improved Coordination Among Federal Agencies

Beyond a national strategy, substantial progress has been made in completing operational guidance and related plans to coordinate agencies. Congress and the President both have recognized the need to review and clarify the structure for overall leadership and coordination.² A number of previous GAO recommendations that the federal government complete interagency operational guidance have been implemented. Progress also has been made by some individual agencies that have completed or are developing internal plans and guidance.²

According to a 2001 Government Accountability Office report, “However, coordination of federal terrorism research, preparedness, and response programs is fragmented, raising concerns about the preparedness of states and local units to respond to a bioterrorist attack.”²² Concerns also include insufficient state and local planning and a lack of hospital participation in training on terrorism and emergency response planning.²²

Inherent challenges remain in managing federal programs and resources to combat terrorism. First, numerous federal agencies have some role in combating terrorism. Second, these federal agencies represent different types of organizations, including those involved in intelligence, law enforcement, military matters, health services, environmental protection, emergency manage-

ment, and diplomacy. Another challenge in coordinating budgets to combat terrorism is that funding for these programs is also used for missions unrelated to terrorism.²³

The Need for Improved Civilian-Military Coordination

PDD 39 of 1995 established an early model for what would become the watershed event for U.S. federal coordination of civilian and military counter-terrorism efforts during the 1996 Atlanta Olympics.^{9,24} The 1996 Defense Against Weapons of Mass Destruction Act provided that after 3 years the function could be transferred from the U.S. Department of Defense to some other lead agency with the President’s approval. The transfer was made to the Department of Justice in 1999, and the Office of State and Local Domestic Preparedness became the lead. Both FEMA and this organization are now part of the Department of Homeland Security.

In 2000, the second annual Gilmore report recommended clarifying the role of the military in domestic terrorism response.¹⁸ In 2004, Burkle and Noji²⁵ also cited difficulties involving coordination of civilian and military assets during war in Iraq.

The Need for Improved Regional Coordination

Strategic plans developed by regional organizations can be effective tools to focus resources and efforts to

address problems. Given the important role that regional planning and governance can play in improving national preparedness, these developments warrant continuing Congressional oversight.²⁶

Occupational Health and Safety Are Critical to Effective Disaster Response

During the anthrax emergency of 2001, nine postal employees associated with two postal facilities that processed tainted letters contracted anthrax, and two employees died. According to a 2004 Government Accountability Office report, "The response to anthrax contamination revealed several lessons, the most important of which is that agencies need to choose a course of action that poses the least risk of harm when considering actions to protect people from uncertain and potentially life-threatening health risks."²⁷ The World Trade Center attack of 2001 also resulted in a very high occupational health risk to workers.^{28,29}

Coordination of Public Information Is a Formidable Challenge

During the anthrax emergency, from October 8 to 31, 2001, the CDC's emergency response center received 8860 telephone inquiries from a wide cross section of society in all 50 states, the District of Columbia, Puerto Rico, Guam, and 22 foreign countries. While local and state officials reported that the CDC's support of their responses to the rapidly unfolding anthrax incidents at the local and state levels was generally effective, the CDC acknowledged that it was not fully prepared for the challenge of coordinating the public health response across the federal agencies. The CDC experienced difficulty serving as the focal point for communicating critical information during the response, and spokespersons for the agency described having to create an ad hoc emergency response center in an auditorium from which to manage the federal public health response, which involved numerous agencies. The CDC also had difficulty managing the influx of information to produce and disseminate guidance rapidly and had difficulty conveying information to the media and public.⁵

Interoperability and Robust Methods of Communication Are Difficult to Maintain

The need for common, agreed-upon standards is widely acknowledged in the health community, and activities to strengthen and increase the use of applicable standards are ongoing. Despite ongoing efforts to address information technology (IT) standards, many issues remain to be worked out, including coordinating the various standards-setting initiatives and monitoring the implementation of standards for healthcare delivery and public health. An underlying challenge for establishing and implementing such standards is the lack of an overall strategy guiding IT development and initiatives.³⁰

U.S. Preparedness Varies from State to State

The anthrax incidents during the fall of 2001 raised concerns about the nation's ability to respond to bioterrorist events and other public health threats. Several months after the incidents, the U.S. Congress appropriated funds to strengthen state and local bioterrorism preparedness. However, preparedness varies significantly from state to state.³¹

In 2002, the U.S. Department of Health and Human Services' CDC and Health Resources and Services Administration distributed US\$1 billion in funds through two cooperative agreement programs with state, municipal, and territorial governments. States reported progress toward the CDC programs' goals of strengthening public health preparedness but identified factors that hindered them from meeting all of the CDC's 2002 cooperative agreement requirements. All states reported progress in developing the capacities the CDC considers critical for public health preparedness, but no state completed all program requirements.³²

Disaster Policy and Plans Are Not Always Followed

The anthrax incidents of 2001 required an unprecedented public health response. These biologic attacks on the nation not only affected our government, but also revealed the challenges and shortcomings facing the nation's public health system.

It is important to note that during the anthrax emergency, neither the Federal Response Plan nor the federal Concept of Operations Plan (CONPLAN) for responses to terrorist attacks was used. Under the CONPLAN, the FBI and FEMA play major roles as the lead agencies for crisis management and consequence management, respectively. Although the FBI was very heavily involved in the source letter investigations, the FBI did not exercise its crisis management authorities. FEMA did not serve as the federal lead for consequence management.⁶

New Policies May Result in an Infringement of Civil Liberties of U.S. Citizens

The mandate of increased intelligence gathering and surveillance of U.S. citizens has been met with concerns regarding civil rights, and privacy rights in particular. Some aspects of the USA Patriot Act of 2001 have also been criticized for infringement on civil liberties. Another controversial action of the post-9/11 era was the so-called Carnivore program to intercept cell-phone and Internet transmissions, which still exists in some form despite Congressional efforts to limit or end it.

Repeated Threat Advisories May Result in "Warning Fatigue"

HSPD-3: Homeland Security Advisory System was designed to provide an effective means to disseminate information

regarding the risk of terrorist acts to federal, state, and local authorities and the American people by providing warnings in the form of a graduated set of “Threat Conditions” that change as the risk changes. Federal departments and agencies implement their “Protective Measures” when there is a change in the status of the warnings.

The warning system has been criticized regarding both its cost and effectiveness. Most importantly, the Threat Condition assignment from the beginning was designed to be based on a qualitative assessment, not quantitative calculation. Higher conditions are to reflect both probability and consequences.

Lack of Hospital Preparedness and the Myth of Surge Capacity

Despite large expenditures to promote hospital preparedness over the past 8 years, there remain significant gaps in surge capacity as well as basic capabilities related to bioterrorism.^{33,34}

The Science and Practice of Disaster Medicine Remain Underdeveloped

Despite all of the recent sociopolitical awareness of the unique and critical mix of disaster management and emergency medicine, disaster medicine remains to date largely underdeveloped as a medical subspecialty. Increased awareness and extensive federal funding for public health and medical preparedness and response have translated into a broadened involvement of postgraduate academia. But, disaster medicine has not matured into subspecialty board or certification status of medicine or public health.

The Psychology of Terrorism

Robert A. Ciottone

Terrorism is an elusive term to define, one that seems “far too nimble a creature for social science to be able to pin it down in anything like a reliable manner”¹ Experientially, however, terror has a shared and familiar meaning within everyone’s frame of reference. The origins of those feelings may be recent or they may be remote and only dimly recalled under the usual conditions of everyday life. Nevertheless, every individual within a population either is or has been the child who fears monsters lurking in places that cannot be seen clearly. Because of the universality of such experiences, feelings of terror remain potentially resurgent for every person.

Terrorists seek to destabilize population groups by a variety of means. One method is to resurrect through their actions the primitive and enveloping fears associated with the sense that “monsters” may act unpredictably and with impunity. Further, terrorists seek to imbue the destabilizing impact of such events for both individuals and for societal institutions with sustained, destructive energy. Although terrorist-driven occurrences are temporally circumscribable, the psychological effect of terrorism is more a process than an event. A host of factors conspire to perpetuate the psychologically destabilizing effect of terrorism long after a focal event has occurred. These include uncertainty about the potential for and the possible timing of renewed attacks, disruption of infrastructure upon which many have relied, fears that health services may become overtaxed and unavailable when they are most needed, and concern about loved ones in areas presumed to be particularly vulnerable.

Problematic psychological reactions to destructive terrorist-driven occurrences are not restricted to individuals who directly witness the event or who are affected by it in a relatively direct manner. Indeed, “media coverage of major terrorist events tends to be intense, capturing acute suffering and vulnerability. Unlike fictional stories, it portrays actual events and is sometimes unedited. And it produces the images of death and destruction that instill fear and intimidation in the larger public.”² At the very least, the psychological effects of disastrous events can severely tax the ability of those affected to function with a level of efficiency that characterized their pre-event baseline.³ Moreover, erosion of that efficiency may persist for many months and perhaps

much longer, particularly with regard to incidence rates of psychiatric dysfunction and/or of stress-related physical illness within an affected population.

HISTORICAL PERSPECTIVE

Terrorism has been defined as violence involving attacks on a small number of victims in order to influence a wider audience.⁴ Much that has been written about the psychology of terrorism has centered on the emotions, motivations, cognitions, and other aspects of the psychological profile of those who would perpetrate such violence. As Cooper⁵ noted, “The true terrorist must steel himself against tender-heartedness through a fierce faith in his credo or by a blessed retreat into a comforting, individual madness.” If the presumed gift of a wooden horse that secretly held in its belly attackers who were bent on surprise and violence qualifies by this definition, the roots of terrorism stretch back through antiquity. More recently, in the centuries from the Middle Ages to the Industrial Revolution, warfare was conducted according to an implicit code of rules that sought in its most caricatured instances to render military conflict a “civilized affair,” however much of an oxymoron that phrase might have been even in days past. Eventually, international organizations such as the League of Nations and later the United Nations came about in part out of a need to hold conflict within some bounds, even if it could not be eliminated entirely. Further, the Geneva Convention sought explicit agreement to rules of conduct on the part of potential adversaries before conflict had even emerged.

The goals underlying such efforts have proved elusive at best. As Crenshaw⁶ noted, “Significant innovations” in terrorism occurred in 1968 with the onset of relatively routine diplomatic kidnappings and hijackings involving extortion or blackmail. The pattern of increase in terrorist activity since that time, and to the present has been all too familiar. Silke¹ has strongly argued the importance of researching this phenomenon with all of its implications. Having reviewed the literature, however, Silke,⁷ like Merrari⁸ before him, found that systematic inquiry by psychologists and psychiatrists fell short of what seemed to be needed.

Notwithstanding the importance of inquiry into factors related to the development of individual and group manifestations of terrorism, the focus here is on its psychological effect on the affected population who will look to emergency medicine for care. The goal of this chapter is to consider psychological factors related to the effect of terrorism on a population. Although some specific guidelines may be derived from a conceptualization of that sort, the purpose is rather to develop an awareness of psychologically contextual issues that may productively inform, although not necessarily direct, the judgments and decisions of service providers functioning in a terrorist-driven circumstance.

CURRENT PERSPECTIVES

First responders and caretakers are clearly among those in the population who can be affected most directly by terrorist events. Not only do they share in the danger of feeling overwhelmed and in the risk for problematic reactions, they also bear the expectations of others to remedy what might seem to be an impossible situation at times. Further, they share with those to whom they provide services the need that the toll taken by terrorism upon them be monitored and managed. The alternative—of implicitly adopting the false notion that first responders and medical practitioners are somehow above the psychologically harmful effect of terrorism or immune to it—invites multiple problems that have the potential of proliferating because of their effect on the service function. Accordingly, in the context of responding to terrorism, one of the imperatives for emergency medicine personnel must be to attend to the psychological needs of peers and of subordinates. For them, the sustained nature of the problem can exact a toll far exceeding the accustomed demands of providing emergency care.

Although the psychological effect of terrorism for both individuals and societal institutions can be considered in its various aspects, an over-arching concept would provide coherence to considerations that might otherwise seem scattered. One such conceptually unifying theoretical perspective is the *orthogenetic principle*, a holistic developmental notion first articulated by Werner⁹ and later by Wapner and Werner.¹⁰ Essentially a *meta-theoretical* notion, the orthogenetic principle was subsequently elaborated by Wapner,¹¹⁻¹³ and by Kaplan, Wapner, and Cohen.¹⁴ Briefly stated, that principle holds that *all that occurs through development proceeds from the global and diffuses through increasing states of differentiation and hierarchic integration*. In this context, “development” is not temporally defined nor is it tied to chronometry. Instead, the principle applies to any developmental phenomenon ranging, for example, from the microgenesis of thought behind each word spoken to the experience of an overall self-world relationship throughout the life span.

Through the prism of the orthogenetic principle, the developmental continuum from diffuse through integrated is conceived of as a dynamic one within the context of which is the potential for developmental advance

(toward increased integration) and/or de-differentiation (regression to a more primitive developmental level). Movement forward (developmental advance) and/or movement backward (developmental regression) is not a discrete event but an ongoing process. Each advance in the direction of increasing differentiation brings with it the requirement that the parts of experience be hierarchically integrated (i.e., subordination of the differentiated parts to the whole) in a yet more refined fashion. Conversely, de-differentiation leads to a less integrated experience with a correspondingly less refined sense of part-whole and of means-ends relationships and of the instrumentalities available for transacting with the environment thus construed. Developmental advance along that continuum brings with it an increasing sense of mastery, whereas de-differentiation or regression to a more developmentally primitive level invites a growing sense of feeling overwhelmed.

Within that frame of reference, terrorism can be seen as an effort to bring about de-differentiation and correspondingly more developmentally primitive functioning within populations and among the individuals that comprise them. Accordingly, interventions intended to address terrorism and its effects can be characterized as more or less facilitative of developmental advance and, correspondingly, of some increased level of mastery.

Acts of terrorism result psychologically in both direct and indirect destructive consequences of the sort that bring about developmental regression to a relatively less differentiated sense of one’s relationship with the surroundings. The direct consequences typically have a powerful immediacy in their effect on the consciousness of affected segments of the population. Those consequences may well prove precipitously de-differentiating in their assault on the sensibilities of those persons who are affected. Indirect effects, on the other hand, can be less apparent, particularly in the immediate aftermath of the disaster, but their destructive influence on the population and upon its institutions may be equally, if not more, disruptive to the functioning of the society.

The orthogenetic principle provides, in effect, a reference point by which to gauge and monitor the psychological harm done by terrorism as well as the potential efficacy of efforts intended to mollify the psychological impact of sudden and disastrous terrorist-driven events. Initially, consideration must be given to the psychological vulnerabilities of individuals and/or of groups with regard to the risk of developmental regression. In other words, what has been the effect of trauma and of related fears upon individuals’ cognitive, emotional, and evaluative perceptions of and transactions with the physical, interpersonal, and sociocultural aspects of their surroundings? Stated differently, what changes have occurred with regard to what those affected by terrorism know with some confidence about the objects and places in their surroundings, how have their feelings about them changed, and what shifts have occurred in their attaching relative importance or unimportance to those objects and places? Likewise, how have knowing, feeling, and valuing shifted with regard to the interpersonal environment and in relation to their perceived environment of customs, responsibilities, and expectations? Second, how

might a particular effort foster developmental advance in these areas? In other words, what is the best way to facilitate movement toward an approximation of pre-event psychological baseline?

The direct effects of terrorism are closely linked to the physical realities of the event (explosions, collapse of buildings or other structures, infectious outbreaks, etc.). According to Shalev,¹⁵ however, traumatic events such as acts of terrorism can also be described according to their psychological dimensions. The two are obviously intertwined. Indeed, as Shalev has also noted, "Shortly after exposure, the traumatic event ceases to be a concrete event and starts to become a psychological event."¹⁵ Physical injuries, often of a mangling and grotesque sort, together with the tragic loss of lives, typically become the signature of the event in the popular mind. Those images serve as a reference both for on-site survivors and, as a result of media coverage, for those who learn of the disaster from a distance. Moreover, such images can quickly become an experiential template onto which both proximate and remote observers project their own sense of vulnerability and/or that of their loved ones. In the context of responding to terrorism, therefore, emergency interventions on behalf of victims as well as the ancillary and administrative procedures established to support them should emphasize not simply the reactive measures taken, but proactively oriented steps as well. The goal is to impart the promise of mastery of the circumstance by conveying some sense that those acting as agents for the well-being of the affected remain able to act on their behalf. By the very nature of terrorism, some of those efforts may have to be shaped on an *ad hoc* basis. Even in that circumstance, however, it is important to establish and maintain an approach that is consistent in both appearance and substance with a relatively differentiated response, rather than one that conveys a global, diffuse, and relatively undifferentiated quality.

The destruction of property and infrastructure, the limits imposed on transportation, and the disruption of communication typically serve to further compound the effect of terrorism on the accustomed behavior patterns of those sectors of society that have been affected directly. In effect, individuals as well as groups and organizations may be severely limited in the use of accustomed instrumentalities that they have habitually used as a means of transacting with their surroundings. Regression to developmental primitivity is a distinct risk for those persons and institutions thus deprived of the tools by which to manage ongoing experience and to meet needs that have been readily satisfied in the past.

Developmental de-differentiation in the wake of terrorist-driven events and the resulting increase in stress that may in turn compromise health can also result from sociological factors. In the past, populations could be expected to unite when confronted with a common foe. Attacks or states of siege were typically seen as the work of "outsiders." As a result, those who comprised the population attacked were the "insiders," united at least to that degree and able to take some measure of comfort from the availability and presumed good will of neighbors. In a terrorist environment, however, there is the distinct danger that neighbors may seem suspect. "Cells" of ter-

rorists may operate anywhere and, as a result, danger may be perceived as potentially stemming even from those who seem to be "insiders" or members of the same targeted population. As a result, the cohesiveness that usually occurs within a population on the heels of an attack may be severely compromised. Further, anyone exhibiting characteristics similar to those associated with the assumed perpetrators of the terrorism may become the object of suspicion, if not attack. Backlash effects can then lead to divisiveness and thereby compound the resulting stress experienced by individuals within the population. Given the demonstrable relationship between stress and health, it is incumbent upon caretakers and service providers to remain mindful of this potential psychosocial complication and to temper their interventions with sensitivity.

These and other direct effects of terrorism can severely tax and compromise the psychological resources and abilities required to cope with the demands of daily living. The resulting de-differentiation would be further compounded if some semblance of pre-disaster infrastructure and service capability is not restored relatively soon after the focal event or if no believable estimation is issued as to when such restoration will occur. Accordingly, an important part of an effective emergency response includes providing accurate information regarding system level plans and prospects for returning to a pre-event baseline of service delivery. Although meeting this requirement of comprehensive care might be subsumed under the principle of providing reassurance, it is important from a developmental perspective that it not be trivialized. Further, it is important that information provided not be false or contrived, particularly since subsequent determination of intentionally misleading facts having been provided would probably compound the psychological damage it may have been intended to relieve.¹⁶ Instead, a straightforward acknowledgement that information is not available is much more helpful, particularly when accompanied by an indication that facts will be sought out and shared when they become known.

Offering reassurance without misleading patients is a concern that applies to all aspects of clinical care. Providing services in response to terrorism is no exception. In fact, by virtue of the sense of the potentially overwhelming danger that seems to linger in the wake of terrorist-driven events, that requirement, particularly when viewed from a developmental perspective, becomes a salient one. To err by presenting patients with excessive ambiguity invites the projection of fears that might be much more extreme than the reality, however harsh. Such projections could well prompt developmental regression in the experience of self-world relationships. On the other hand, the other extreme of seeking to reassure patients by straining the limits of believability cannot only destroy trust and encourage regression, but can also render its future restoration difficult at best. Accordingly, patients' psychological well-being and developmental advance are best served by clinicians relating with honesty tempered by empathic consideration for patients' subjective experience.

Observable instances of terrorism differ in terms of the degree and extent of their physical destructiveness. More

circumscribed acts of terrorism such as a bomb being detonated outside a police station or a polling place would obviously have a correspondingly less pervasive and/or less extensive impact on infrastructure and on the operation of societal institutions. Developmental regression, however, remains a danger. Those individuals upon whom the event directly impinges by its actual occurrence or by the fear that its having been threatened was intended to cause might well experience a disruption in their perception of "self-world relationships" and in their ability to manage themselves productively. Their reaction, in other words, could prove analogous to that which would likely occur on a larger scale in the wake of more extensive incidents. Moreover, even those not directly affected by the event could well come to experience themselves as operating in a context of potentially sudden and unexpected hazard such that their actions might well become more tentative and fearful and less purposefully goal oriented.

Indirect, destructive effects of manmade disasters are often subtle and insidious in their erosive effect on the developmental level of functioning of societal institutions as well as on that of the individuals within them. The frequent absence of immediate and overt indications of those effects notwithstanding, disruptions in cognitive, emotional, physical, and behavioral functioning in significant segments of the population can be anticipated in the aftermath of a terrorist event.¹⁶ These may be sustained by lingering (if not growing) fear, and by feelings of helplessness in the face of an unseen and perhaps unidentified perpetrator who may strike again with no warning. The resulting perception of risk represents a strong challenge to the capacity of individuals and of groups to cope with the demands of everyday life with the same level of efficiency that characterized their pre-event behavior. As a result, clinicians may well note that lapses will occur in patients' (as well as in peers' and subordinates') previously accustomed patterns of judgment, decisiveness, establishing and maintaining priorities, and other related psychological functions.

Organizations as well as individuals are likely to experience these changes to varying degrees. Such effects may very well linger for a significant period after the terrorist event. For those in authority to provide supportive oversight of groups assigned various responsibilities therefore takes on an even greater importance than usual.

Indirect effects of a manmade disaster also include a significant increase of pressure upon public health systems for resources and services. Those demands typically occur in two phases. First is an obvious requirement to respond to direct casualties of the disaster. It is necessary, however, to also anticipate a predictable increase in stress-related illness that typically follows such events. In addition to psychiatric reactions such as depression and posttraumatic stress disorder, rates of physical stress-related illnesses also rise when the psychological resources of a population are taxed by trauma.¹⁷ Psychiatric problems, not restricted in their increased incidence to the immediate aftermath of focal terrorist events, tend to increase within a traumatized population about 3, 6, and 18 months after the event. The increased incidence rates of these and of stress-related physical illnesses in particular may well extend much further.¹⁸

Accordingly, planning for health care within a population exposed to a man-made disaster must adopt a long-term view that takes the continuing effect of trauma on the health of an exposed population into account.

When negligence or incompetence results in death and/or destruction, those who perceive themselves as being at risk from its recurrence are likely to experience emotions ranging from fear and anger to distrust of societal institutions and their stewards. Intentional events of destruction such as acts of terrorism, however, may well have even more disruptive psychosocial effects, both immediate and delayed. Similarly, the devastation wrought by a naturally occurring disaster may be greater in terms of casualties and damage to infrastructure, yet the psychological impact of the terrorist-driven may still prove more extensive. Why is this the case? One reason has to do with perceived intentionality on the part of the potential causal agent of the danger.

A central tenet of most teleologically oriented theoretical perspectives in psychology (including the holistic developmental system of conceptual constructs) is that individuals impose meaning upon their experience and that they transact with the surroundings thus construed.¹⁹ When the source of a seemingly amorphous but apparently present danger is perceived as intentionally malevolent, the safety of self and of others feels particularly at risk. When that potential source of danger is hidden from view and perhaps anonymous as well, feelings of fear and helplessness are further compounded. Moreover, locations usually perceived as safe provide little comfort and do not satisfy the wish to hide in protected places.

It is important to recall that problematic reactions to destructive occurrences are typically not restricted to individuals who directly witness the event. As previously noted, media coverage of events may in some ways leave those who are more distant with an even broader and potentially more de-stabilizing view than is available to those who are closer to the event but whose view of it is less expansive. In either case, the psychological effects can severely tax the ability of those affected to function with a level of efficiency that characterized their pre-event baseline. Further, persons affected by virtue of their relatedness to victims of a disaster and/or by disruption of their relationship with societal systems affected by the disaster (e.g., supply systems for food, water, medical services) may be at extreme risk for problematic reactions. Specifically, they may well be left in an ego-dystonic state of perceived inefficacy, vulnerability, and dysphoria.²⁰ Those effects can be profound. Indeed, those who remain thus affected for 1 year may not recover.²¹

As noted previously, one consequence of the de-differentiating effect of exposure to critical events upon perception is to reactivate developmentally primitive perceptual tendencies and to vaguely recall fears that were prominent during childhood. The reasons for that frequently evident phenomenon are straightforward. Every individual has, at some time in her or his life, experienced a profound and panic triggering sense of helplessness in the face of what seems to be overwhelmingly threatening. Given the continuing availability of that frame of reference, terrorists who are intent on wreaking havoc and who seem to strike without warning may

recall the feelings that perhaps long ago were as overwhelming as they might be to the child who was fearful of monsters in the shadows. Just as the child looked to a parent to “put on the light” and check for danger, those affected by a terrorist event look to authorities for reassurance. They seek to put aside their feelings of terror, and, to some degree, to master the ongoing experience to some degree. Moreover, just as the child needed reassurance on more than one occasion, populations look to perceived authorities such as service providers for repeated signals that problems are being addressed.

PITFALLS

Clinicians are, by the nature of their responsibilities, obliged to remain alert to the signs that pressures are giving rise to stress that has the power to potentiate physical illness and/or to retard healing. To be sure, “pressure” and “stress” are often used as interchangeable terms as if they were fully synonymous. To say “I am under stress” carries that implication. In one sense, however, pressure differs from stress in that pressure impinges on people. Stress, on the other hand, can be seen as a quality of the response that is made by individuals trying to manage pressure. The distinction is more than semantic; it is an important one because it implies that some measure of control over stress is possible, independent of the pressures that may operate outside of one’s control. The psychological pressures associated with terrorism can obviously be extreme, but an effort needs to be made nonetheless to intervene in ways that, to the extent possible, minimize the extent to which those pressures are translated into stress and thereby into increased vulnerability to related illness.

What might be anticipated when the pressures related to terrorism become pathogenic sources of stress? Among the most frequently occurring, posttraumatic stress disorder (PTSD) represents one very prominent problematic sequellum associated with exposure to terrorism.²² Those who have been directly exposed to traumatic events are at greatest risk for developing PTSD, particularly if they have experienced physical immobility and/or helplessness while trying to escape; or if they have first-hand experience of the sounds, smells, and images; or if their lives have been permanently altered by the death or injury of a loved one.²³ Among those working in concert with emergency medicine providers, even the anticipation of handling of bodies and body parts after violent death can foreshadow PTSD.^{24,25}

The signs of PTSD may include excessive excitability and arousal, emotional numbing, repetitive intrusive memories of the trauma, and a general inability to function with the efficiency that was typical prior to the trauma. From a diagnostic standpoint, PTSD is evident when these and related symptoms persist for at least 1 month and when significant distress results from them (DSM IV). The persistence of symptoms differentiates PTSD from acute stress disorder (ASD), which involves a clinically significant response to trauma similar to that seen in longer-term stress disorders (i.e., at least 2 days but no longer than 4 weeks).²⁶ The most recent revision

of that diagnostic reference allows for a kind of second-order effect by including affected family members of those who suffered the event directly and emergency workers who responded to their needs as being among those considered potential victims of PTSD.

According to Muldoon,²⁷ some studies suggest that the distress that foreshadows the development of PTSD in fact may be cumulative in a trans-generational sense. Israeli soldiers for whom one or both parents were holocaust survivors, for example, showed a higher incidence of PTSD.²⁸ In a potentially related way, children of Vietnam veterans who had experienced particularly high levels of stress in that conflict showed higher levels of behavioral disturbance.²⁹

Early warning signs of PTSD include memory disturbances that may involve even previously automatized means-ends and part-whole perceptions and behavior sequences. Additional indicators may include flashbacks and traumatic dreams, episodic presentation of a seemingly dissociated or dazed appearance (e.g., the “thousand mile stare”), the emergence of panic attacks, fears, irritability, and tendencies to “self medicate” (i.e., substance abuse).

Developmental regression as a function of the effect of terrorism may first emerge as somewhat less specific antecedents to the symptoms associated with PTSD and/or with other problematic sequelae. As outlined by the Critical Incident Stress Foundation,¹⁶ the tendencies that become evident when stress begins to take a toll will most likely include disruptions in *cognitive functioning*, such as confused thinking, disorientation, indecisiveness, and difficulty establishing priorities. Difficulties with *emotional functioning* that will most likely become evident may include feeling overwhelmed and unable to manage, extreme anger and/or grief, a pervasively and persistently depressed mood, etc. *Physical functioning* may well reflect problems that include increased blood pressure, increased heart rate, dizzy spells, rapid breathing, etc. Adverse effects on *behavioral functioning* may lead to changes in eating and sleep patterns, interpersonal withdrawal, changes in behavior patterns associated with the activities of daily living, etc.

What are the implications of this aspect of a patient’s problematic psychological response for clinicians trying to address the consequences of terrorism? How might the lingering perception of continuing risk from recurrent events be managed? How best to mobilize and direct patients’ energies to facilitate recovery rather than to allow those energies to be spent in diffuse anger or transformed into feelings of helplessness? In addressing these and related matters, clinicians’ efforts should be shaped by an ongoing monitoring of the extent to which developmental de-differentiation is being averted and developmental advance is instead being fostered.

From the outset, clinicians must adopt a manner, particularly in communication, that conveys a determination to focus on resolving the problem. It is also important to “put on the light,” as it were, to offset the potential for resurgence of archaic fears that monsters lurk in the shadows. This can be accomplished in part by providing information that does not compromise honesty but which nevertheless conveys the message that gains are being

made. At a systematic level as well (and with particular reference to the needs of peers and subordinates), the efforts made by emergency medicine personnel would be well supported by encouraging that information about perpetrators to be made public once some reasonable level of certainty about its accuracy can be assumed. As van der Kork²³ has noted, "After safety is assured, psychological intervention may be needed. People have to learn to put words to the problems they face, to name them and to formulate appropriate solutions."

When ambiguity persists and rumor holds sway, fears can be projected that are so extreme as to invite re-traumatization. The importance of dispelling ambiguity notwithstanding, however, identification should not be made in ways that might encourage wariness and distrust because of reliance on categories such as ethnicity, religious affiliation, etc. Such groupings do little or nothing to assuage anxiety and may, in fact, lead to its exacerbation because of their infusing potential alarm into categories that have been otherwise relatively benign within the population affected by terrorism. Instead, citing the allegiance of terrorists groups to shared goals of de-stabilization and to the use of terrorist methods in the service of a specified cause might be a useful supplement to providing the names of perpetrators if available in the process of identification. By this means, stress is less likely to be compounded by the relatively undifferentiated formlessness of those who would do harm.

To label that which is unknown is to impart some sense of mastery and control. Those who might otherwise be immobilized to some degree by fear can then use the label to perceive an otherwise amorphous threat as one that at least has a name and, thereby, some boundaries and limits to its potential malevolence. Fear then takes on a more circumscribed and seemingly more manageable form. Conversely, in the absence of a name for the potential danger, the sense of jeopardy and the stress-inducing need for sustaining a state of heightened vigilance increases.

Not all victims of terrorist-driven events suffer developmental de-differentiation resulting in stress-related dysfunction or physical disease. According to van der Kork,²³ however, "almost everyone is perturbed during the aftermath of a trauma, and everyone experiences a degree of intrusiveness and sadness." Many others, however, have a much more difficult time "getting over it." In addition to PTSD, consequences of exposure to such events can include depression and disabling, treatment-resistant symptoms of fear and anxiety as well as marital crises and other relationship problems.¹⁷ Accordingly, "Understanding the mechanisms of mental traumatization is extremely important when seeking to evaluate and assist the recent survivor."³⁰

To rely primarily on the verbal re-framing of experience in an effort to provide psychological assistance in the wake of trauma may well prove less than productive, particularly in the early stages of intervention.³¹ In fact, studies have shown that high levels of arousal, such as those associated with trauma, result in frontal lobe functions being suppressed,^{32,33} as are Broca's area functions, which are needed to put feelings into words.³⁴ Subcortical centers, on the other hand, have been impli-

cated as more prominent in the neuropsychological mediation of trauma, particularly with regard to the limbic system.^{35,36} Accordingly, Shalev¹⁵ has noted that soothing bodily contact with the recently rescued is often helpful, but gender and social boundaries must be respected. Bringing in relatives of victims and others close to them may be especially helpful in this regard with caregivers serving as coaches. By these means, a relatively more differentiated and integrated sense of the relationship between the self and the physical, interpersonal, and socio-cultural aspects of the environment can be fostered and maintained. For this reason, "The first role of a therapist is to assess the strengths and weaknesses of the survivor's immediate supporters"¹⁵ and to provide them with the support needed. Thereafter, interventions derived from the principles of cognitive-behavioral therapy have been shown to be of more benefit than supportive counseling alone during the post acute phase of early syndrome formation.³⁷

Having particular relevance to the challenge of precluding developmental regression in the wake of exposure to traumatic events, approaches referred to as "debriefing" involve semi-structured group interventions geared toward alleviating potentially de-differentiating distress and thereby preventing pathological reactions. Two approaches, one introduced by Mitchell³⁸ and another by Dyregov,³⁹ have had relatively extensive application. The first, subsequently advanced through the *Critical Incident Stress Foundation*, has been presented as a training program for volunteers who might be mobilized for service in the wake of a disaster, whether naturally occurring or terrorist driven. The process involves several phases, beginning with an introduction during which personal identification takes place along with a definition of expectations, a setting of limits, and an explanation of confidentiality. There follows a "fact stage" during which each participant is asked to describe the event from his or her own perspective and a "thought stage" during which each participant is asked to recall first thoughts as the event occurred. In the "reaction phase" each person is asked to identify the worst part of the experience, one that she or he would erase from memory if possible. During the "symptom phase" that follows, each person is invited to explain how he or she is different because of the incident and to describe how life has been since the event. A teaching phase then takes place during which debriefing team members seek to "normalize" reactions by explaining their predictability as extraordinary characteristics of the circumstance rather than of the experiencing individual. The team also gives suggestions intended to aid recovery (e.g., relaxation and deep breathing exercises). Finally, during a "re-entry phase," team members provide a summarization and encourage cognitive re-framing of the experience to include some positive outcomes (e.g., lessons learned, insights achieved).

Some studies⁴⁰⁻⁴² have failed to show that debriefing prevents stress disorders. Those same studies, however, indicate that most participants recall the sessions as helpful and satisfying. Moreover, Shalev et al.⁴³ found that debriefing significantly reduces concurrent distress and enhances group cohesion.

CONCLUSION

By way of summary, it is important to recall that terrorists seek to de-stabilize individuals and societal organizations by undermining the cognitive, affective, and valuative perspectives that individuals and societal organizations have of the physical, interpersonal, and socio-cultural aspects of the world. In other words, terrorists seek to re-shape the frame of reference by which people know about, have emotional reactions to, and attach relative importance to the world of objects and places, of people and of laws, and of rules, customs, and expectations. To the extent that they succeed, terrorists can compromise the psychological and physical health of individuals and thereby undermine the strength of a society. Accordingly, those in authority, and in particular the health service providers within a society, must make decisions and initiate efforts with judgment that is informed by sensitivity to the importance of both avoiding developmental de-differentiation and of fostering developmental advance.

Medical Intelligence*

Mark E. Keim

DEFINITION

Medical intelligence can be defined as “that category of intelligence resulting from collection, evaluation, analysis, and interpretation of foreign medical, bio-scientific, and environmental information which is of interest to strategic planning and to military medical planning and operations for the conservation of the fighting strength of friendly forces and the formation of assessments of foreign medical capabilities in both military and civilian sectors.”¹

Medical intelligence related specifically to the threat of terrorism has obvious applicability to civilian sectors as well. It involves information as applied to the identification, characterization, and management of the risk as applied to both military and civilian countermeasures against terrorism.

Collection of medical intelligence may include both classified and open sources. Evaluation may involve preexisting publications or ongoing public health surveillance, and it may also include analysis and/or interpretation of well-established or newly gained data. Characterizations may include situational awareness of current events² as well as descriptions of both foreign and domestic medical and public health capabilities and capacity.

HISTORICAL PERSPECTIVE

The Importance of Medical Intelligence

The greatest threat to military forces is often not enemy guns but rather the type of casualty referred to as a disease and non-battle injury (DNBI). The statistics regarding the effect of disease on military operations are remarkable. During the Civil War, an estimated 414,152 deaths were a result of disease, outranking battle deaths by a ratio of over 2:1.³ In his Civil War memoir, then Major Jonathan Letterman—father of modern U.S. military operational medicine—wrote the following passage⁴:

*The material in this chapter reflects solely the views of the author. It does not necessarily reflect the policies or recommendations of the Centers for Disease Control and Prevention nor the U.S. Department of Health and Human Services.

A corps of medical officers was not established solely for the purpose of attending the wounded and sick. . . . The leading idea, which should be constantly kept in view, is to strengthen the hands of the Commanding General by keeping his army in the most vigorous health, thus rendering it, in the highest degree, efficient for enduring fatigue and privation and for fighting.

The following statistics reveal that the threat of disease during military operations had not ceased by the twentieth century:

- Influenza killed 43,000 U.S. military personnel in World War I. In the U.S. Army, influenza accounted for 80% of all casualties during the war.
- 50% of the U.S. marines deployed to Lebanon in 1958 were incapacitated with severe diarrhea.
- 80% of the U.S. sailors deployed in the Suez in 1975 were stricken with dysentery.
- 30% of the U.S. soldiers deployed to the Sinai in 1982 became dehydration casualties.
- 30% of the U.S. soldiers participating in a combined exercise in Botswana in 1992 returned home with spotted fever rickettsiosis.⁴

Clearly, Major Letterman understood that one of the keys to a successful military campaign is the implementation of preventive procedures to reduce DNBI rates. More recently, two widely recognized authorities in military preventive medicine—Llewellyn Legters and Craig Llewellyn of the Uniformed Services University of the Health Sciences (USUHS)—highlighted the four main objectives of a successful preventive medicine program⁴:

- To determine the nature and magnitude of the disease and injury threats in the planned area of operations before deployment
- To identify the principal countermeasures that must be emphasized to reduce the threats to acceptable levels
- To train individuals in the use of these countermeasures
- To rigorously enforce these countermeasures in the operational area

These measures correspond well with processes of analytical risk management, including risk assessment,

countermeasure determination, risk communication, and countermeasure implementation.

The Development of Modern Medical Intelligence in the United States

During World War II the U.S. Army Medical Intelligence Office (under the Army Surgeon General) was responsible for medical intelligence for the U.S. military. In 1963, the Defense Intelligence Agency (DIA) Medical Intelligence Division assumed this mission. In 1973, the DIA underwent a significant reduction in force; the Medical Intelligence Division was abolished and the U.S. Army Surgeon General then assumed the entire medical intelligence mission. In 1982, the Armed Forces Medical Intelligence Center (AFMIC) was officially established as a tri-service intelligence activity. The Army Surgeon General was designated as Executive Agent. In 1992, AFMIC became a "DIA Field Production Activity."⁵

CURRENT PRACTICE

Military Medical Intelligence

The primary source of military medical intelligence in the United States is the DIA's AFMIC now located at Fort Detrick, Maryland. The AFMIC produces finished, all-source medical intelligence in support of the Department of Defense (DoD) and its components, national policy officials, and other federal agencies. Assessments, forecasts, and databases are prepared on worldwide infectious disease occurrence, global environmental health risks, foreign military and civilian health care capabilities and trends, and militarily significant life science technologies.

Infectious disease and environmental health components of AFMIC focus on those infectious diseases and environmental health factors that could degrade the effectiveness of military forces deploying worldwide for contingency, humanitarian relief, and peacekeeping operations. In addition, these worldwide infectious diseases and environmental degradation have national security and policy implications.

Foreign medical capabilities are assessed to include a country's ability to provide medical services and support to its military forces and civilian population. Key elements include foreign military and civilian medical capabilities (e.g., treatment facilities; medical personnel; treatment capability; training, emergency, and disaster response; logistics; medical and pharmaceutical industries; and research and production facilities).

AFMIC's life sciences and biotechnologies components address foreign basic and applied biomedical and biotechnological developments of military medical importance, including biological, chemical, psychological, and biophysical factors. In addition, key areas of interest include foreign civilian and military pharmaceutical industry capabilities and innovations as well as foreign scientific and technological medical advances for defense against nuclear, biological, and chemical warfare.

Medical intelligence is prepared under the DoD Intelligence Production Program (DoDIPP) and managed

by the DIA's Directorate for Analysis and Production. To meet the needs of a diverse consumer group, AFMIC has created a product line providing intelligence via various media: electronic message, CD-ROM, hard copy, and Intelink.

AFMIC's assessments are consulted before troops are deployed to foreign areas for combat, peacekeeping, or humanitarian operations. AFMIC assessments of potential health risks and foreign health care capabilities allow the medical community to plan for the proper prophylaxis (preventive measures such as providing safe water and food and protective measures against insects), health care support, and medical personnel support. AFMIC also provides time-sensitive, finished medical intelligence in response to direct requests from consumers at the national, departmental, or operational and/or tactical levels. Table 55-1 represents a comprehensive listing of traditional sources of military medical intelligence available in the United States.^{4,7}

Civilian medical intelligence

Any small or large outbreak of disease should be evaluated as a potential bioterrorist attack. The cause of a disease or even the occurrence of something unusual may be very difficult to determine, especially if the initial cases are few. Surveillance needs to be more than routine. Infectious disease criteria for differentiation of bioterrorism from natural outbreaks have been well defined in the literature, as well as within Section 6 of Part I of this textbook.^{8,9,11,13} This initial investigation does not always have to be time consuming or involve law enforcement. Simply looking the facts surrounding the outbreak to determine if anything seems unusual or indicates bioterrorism will suffice in most cases.⁸

The most important factors affecting early detection of a bioterrorist event are likely to be the rate of accrual of new cases at the outset of the epidemic, geographic clustering, the selection of syndromic surveillance methods, and the likelihood of making a diagnosis quickly in clinical practice.¹²

National, regional, and local public health departments must be linked in a network of real-time communication with the medical response community, public safety, regional poison control centers, and regional laboratory capacities for integration of information management, passive and active surveillance systems, and epidemiologic investigation. In 1998, Keim, Kaufmann, and Rodgers¹⁴ were the first to propose development of such a comprehensive system as part of the U.S. Public Health Service.

The primary source of civilian medical intelligence in the United States is the Centers for Disease Control and Prevention (CDC). (Table 55-2 represents a comprehensive listing of traditional sources of civilian medical intelligence available in the United States.)¹⁵⁻¹⁹

The role of the U.S. public health system has evolved significantly since September 11 and the anthrax attacks of late 2001. The public health threat associated with the release of chemical, biological, and radiological/nuclear agents has drawn the CDC and the entire public health system into a national security role. The safety and health of people across the United States and around

TABLE 55-1 MILITARY SOURCES OF MEDICAL INTELLIGENCE

SOURCE	PRODUCT	DESCRIPTION
Armed Forces Medical Intelligence Center (AFMIC), Ft. Detrick, Maryland.	Urban Medical Capabilities Study	Includes a map of the urban area, general health information, and locations, descriptions, and imagery of key medical treatment facilities
	Medical Capabilities Studies (MEDCAP)	Comprehensive evaluation of a country's civilian and military healthcare systems
	Quick Response Tasking (QRT)	A way of asking AFMIC for answers not found in published studies. Their phones are secure via STU-III through the TS-SCI level.
	Joint Worldwide Intelligence Communication System (JWICS)	Secure telecommunications system, which links sites throughout the intelligence and operations communities. It allows, among other things, secure teleconferencing.
	Medical Intelligence Imagery Brief (MIIB)	Annotated imagery with derived text describing and analyzing a significant medical event of current interest
	Medical Intelligence Note (MIN)	Provides a brief assessment of important medical developments to meet time-sensitive requirements for support to medical planning and decision-making as well as material research, development, and acquisition
	Life Sciences and Biotechnology	Assesses foreign basic and applied biomedical and biotechnological developments of military medical importance, foreign civilian and military pharmaceutical industry capabilities, and foreign scientific and technological medical advances for defense against CBRNE warfare.
	Medical, Environmental, Disease Intelligence and Countermeasures (MEDIC)	Provides worldwide infectious disease and environmental health risks hyperlinked to the Joint Service-approved countermeasure recommendations, military and civilian health care delivery capabilities, operational information, disease vector ecology information, and reference data
	Health Services Assessment (HSA)	Provides bottom-line assessment of a country's health services capability
	Infectious Disease Risk Assessments (IDRA)	Pre-deployment force protection planning guidance that assesses the baseline risk from infectious diseases of operational military importance on a country-by-country basis worldwide
	Disease Occurrence WorldWide (DOWW)	Short, timely alerts that assess risk to U.S. forces from foreign disease outbreaks that may affect military operations and forecast disease risks associated with recent environmental disasters
	Environmental Health Risk Assessments (EHRA)	Assesses environmental health risks of operational military significance on a country-by-country basis worldwide
	Industrial Facility Health Risk Assessment (IFHRA)	Assesses health risk associated with potential exposure to toxic industrial chemicals at specific industrial facilities worldwide
	Industry Sector Profile (ISP)	Assesses potential environmental and human health impacts related to routine emissions and large-scale chemical releases from industrial activities by industry sector
AFMIC Wire	Toxic Industrial Chemical Risk Assessment (TICRA)	Provides a country-by-country prioritization of industrial facilities based on the potential exposure to toxic chemicals and expected adverse health effects
	AFMIC Wire	A periodic message update that provides analysis of newly reported information of immediate interest to deployed or deploying forces
Defense Pest Management Information Analysis Center (DPMIAC)	Disease Vector Ecology Profiles (DVEP)	Information regarding disease risks, infectious agents, modes of transmission, geographic and seasonal incidence, and prevention and control recommendations
Navy Environmental Health Center	Navy Preventive Medicine Information System (NAPMIS)	A computerized information system designed to support the Fleet and Fleet Marine Force with consistently updated preventive medicine and vector-borne disease profiles of countries of military importance
Walter Reed Army Institute of Research (WRAIR)	Communicable Disease Report	Identifies disease outbreaks worldwide. In addition, WRAIR quickly responds to ad hoc queries and provides timely regional medical information.
U.S. Army Research Institute of Environmental Medicine (USARIEM)	Deployment Manuals	Address soldier health and performance in a wide variety of environments
All national-level intelligence organizations	INTELINK	Described as the "classified on-ramp to the information superhighway." All national-level intelligence organizations have home pages on INTELINK, including AFMIC. In addition, each of the Unified Command Joint Intelligence Centers has a home page.
Assistant Secretary of Defense for Health Affairs (ASDHA) with support from Armed Forces Research Institute of Medical Sciences (AFRIMS)	DoD Global Emerging Infections System (GEIS)	Serves as the focal point for DoD efforts to address emerging infectious diseases. The Military Health System network of clinical and laboratory resources provides infrastructure for GEIS. The emphasis of GEIS is on the strengthening of laboratory-based surveillance, particularly for influenza and other respiratory illnesses, for reportable illnesses, for changes in antibiotic resistance patterns, and for other evidence of emerging infections. DoD overseas laboratories provide forward sentinel surveillance sites for GEIS activities.

TABLE 55-2 CIVILIAN SOURCES OF MEDICAL INTELLIGENCE

SOURCE	DESCRIPTION
Centers for Disease Control and Prevention (CDC) Public Health Information Network (PHIN)	A public health architecture that will coordinate existing and new public health information systems for interoperable use of information technology across public health. PHIN is composed of five key components: detection and monitoring, data analysis, knowledge management, alerting, and response. PHIN will integrate and build on the technical standards and infrastructure established through other CDC/ATSDR initiatives, including EPI-X, NEDSS, and PULSENET.
CDC Epidemic Information Exchange (EPI-X)	A secure web-based communications network for public health officials. Using advanced Internet and communications technologies, EPI-X provides 24 hours a day, 7 days a week (24x7) emergency alerts and creates a protected forum to share important disease information nationwide positioning public health officials to detect and respond accordingly to suspect terrorism emergencies. EPI-X is used as a communication tool by DHHS and CDC/ATSDR emergency operations centers and state terrorism coordinators to exchange routine and emergent public health information with state and CDC/ATSDR public health professionals rapidly and securely.
CDC PULSENET	An early warning system for outbreaks of foodborne disease consisting of a national network of public health laboratories that performs DNA "fingerprinting" on bacteria that may be foodborne. The network identifies and labels each "fingerprint" pattern and permits rapid comparison of these patterns through an electronic database at CDC/ATSDR to identify related strains. PULSENET participants include all 50 state public health laboratories, 5 local public health laboratories, 7 FDA laboratories, the USDA food safety and inspection laboratory, 7 Canadian laboratories and participation from a variety of nations across Europe, the Middle East, Latin America, and the Pacific rim.
CDC Nationwide Chemical Poisoning and Radiological Illness Monitoring System	Working to develop standard protocols to identify and respond to events while enhancing communications among local, state, federal, and other partners, including poison control centers. This early warning system will be sensitive and specific enough to identify cases associated with chemical and radiological exposures. It will include long-term follow-up of potentially exposed subjects and an automated tracking system that provides daily incidence data on symptoms and syndromes that may indicate chemical and radiological exposure.
CDC Biowatch	Assisting the Department of Homeland Security and the Environmental Protection Agency (EPA) to perform 24x7 environmental surveillance using existing EPA and Department of Energy (DOE) air quality-monitoring systems. Air samples will be tested in cities for the presence of biological pathogens to generate early warnings of possible attacks. Implementation consists of three primary components: field (sampling devices, collection, transport, and verification), laboratory (processing and polymerase chain reaction, PCR analysis), and consequence management. Laboratory response network confirmatory-level labs will conduct the necessary laboratory analyses.
CDC Laboratory Response Network (LRN)	A consortium of laboratories comprised primarily of state, local, and federal public health laboratories, each with different capabilities and levels of expertise. As a network, it provides immediate and sustained laboratory testing and communication in the event of public health emergencies, particularly in response to acts of terrorism. Members belong to different agencies and jurisdictions but are unified by a common system of operations.
CDC Health Alert Network (HAN)	An e-mail messaging and distribution structure that ensures local health departments have timely and rapid access to emerging health information in order for the frontline professionals to effectively translate the data into health action. HAN provides three primary capacities: (1) high-speed internet connectivity, (2) broadcast capacity for emergency communication, and (3) distance-learning infrastructure for real-time training.
CDC National Public Health Information Coalition (NPHIC)	Activities include scheduling routine teleconferences to discuss and coordinate communication about specific agents currently or potentially of concern, establishing a secure section of the NPHIC website to allow members to post and exchange information about communication needs and resources around specific events, and providing input to such emergency response planning efforts as the ASTHO anti-terrorism task force.
CDC Emergency Communications System (ECS)	Ensures rapid, effective, and consistent CDC/ATSDR communication response to the news media, the public, and key stakeholders in the event of terrorism or a national public health emergency.
CDC Early Aberration Reporting System (EARS)	A widely used syndromic surveillance tool. City, county, and state public health officials in the United States and abroad currently use EARS on syndromic data from emergency departments, 911 calls, physician office data, school and business absenteeism, and over-the-counter drug sales. The EARS program presents its analysis in a complete HTML website containing tables and graphs linked through a home page.
CDC Health Information for International Travel	A document often referred to as the "Yellow Handbook," which identifies current vaccination requirements, immunization and prophylaxis recommendations, and regional health hazards.
CDC Morbidity and Mortality Weekly Report (MMWR)	Contains data on specific diseases as reported by state and territorial health departments and reports on infectious and chronic diseases, environmental hazards, natural or human-generated disasters, occupational diseases and injuries, and intentional and unintentional injuries.
US Department of State Country Background Notes	Provides information on geographic entities and international organizations. It is updated periodically.
World Health Organization (WHO) Vaccination Certificate Requirements and Health Advice for International Travel	Identifies current vaccination requirements, immunization, and prophylaxis recommendations as well as regional health hazards.
WHO Weekly Epidemiological Record (WER)	Instrument for the rapid and accurate dissemination of epidemiological information on cases and outbreaks of diseases under the International Health Regulations and on other communicable diseases of public health importance, including newly emerging or reemerging infections.

TABLE 55-2 CIVILIAN SOURCES OF MEDICAL INTELLIGENCE—Cont'd

SOURCE	DESCRIPTION
iJET Travel Risk Management	1. Provides corporate staff and employees tactical information and reports for more than 180 countries and 260 cities to help travelers avoid disruptions and to stay safe, healthy, and productive.
1. Travel Intelligence Services	2. Provides corporate security, travel, and human resource personnel the ability to track, locate, and communicate with travelers at all times, anywhere in the world.
2. Worldcue Risk Management System	3. Provides both response capability and proactive risk mitigation services, such as consulting, contingency planning, training, and intelligence.
3. GlobalGuardian	

the globe demands the best science, immediate public health service, and a sound strategy to prepare for and respond to terrorist threats.

With the realization that the threat of bioterrorism was increasing, the CDC developed a strategic plan for preparedness and response to terrorism. The CDC centers, institutes, and offices contribute their expertise toward this effort, by improving¹⁵:

- Detection and investigation
- Prevention programs
- Worker safety
- Laboratory sciences research
- Communication
- Workforce development
- Long-term consequence management

Terrorism-preparedness activities described in CDC's strategic plan include the development of a public health communication infrastructure, a multilevel network of diagnostic laboratories, and an integrated disease surveillance system.²⁰ These are remarkably similar to the 1998 recommendations of Keim, Kaufmann, and Rodgers.¹⁴ Surveillance systems collect and monitor data for disease trends and/or outbreaks so that public health personnel can protect the nation's health. CDC now maintains several effective surveillance tools and systems that can be used to gain medical intelligence for the detection and characterization of terrorism. CDC is also now working with state and local health departments and information system contractors to develop real-time special event syndromic surveillance and analytical methods. Throughout the planning documents developed for bioterrorism response, veterinarians are also considered as a key part of the disease surveillance system.²¹

Methods for conducting public health surveillance may differ considerably by program and disease. Regardless of these differences, however, all surveillance activities share many common practices in the way data are collected, managed, transmitted, analyzed, accessed, and disseminated. CDC's long-term vision is that of complementary electronic information systems that automatically gather health data from a variety of sources on a real-time basis, facilitate the monitoring of the health of communities, assist in the ongoing analysis of trends and detection of emerging public health problems, and provide information for setting public health policy.

Currently there are multiple systems in place that support communications for public health labs, the clinical

community, and state and local health departments. Each has demonstrated the importance of being able to exchange health information. However, many of these systems operate in isolation, not capitalizing on the potential for a cross-fertilization of data exchange. CDC is working to provide a cross-cutting and unifying framework to better monitor these data streams for early detection of public health issues and emergencies. Ensuring the security of this information is also critical, as is the ability of the network to work reliably in times of national crisis.

A bioterrorist attack, like other health threats, would be detected first at the local level. Health departments throughout the nation must be prepared to detect and respond to those threats. CDC has established a communications, information, distance-learning, and organizational infrastructure in partnership with the National Association of County and City Health Officials (NACCHO), the Association of State and Territorial Health Officials (ASTHO), and other health organizations for a new level of defense against health threats, including the possibility of bioterrorism. CDC officials, state and local health departments, poison control centers, and other public health professionals can now access and share preliminary health surveillance information quickly and securely. Users can also be notified actively of health events as they occur.

Most biological agents can be diagnosed at standard hospital clinical laboratories.²² CDC has established a consortium of laboratories comprised primarily of state, local, and federal public health laboratories, each with different capabilities and levels of expertise.²³ National laboratories, including those operated by the CDC and the U.S. Army Medical Research Institute of Infectious Diseases (USAMRIID), are responsible for specialized strain characterizations, bioforensics, select agent activity, and handling of highly infectious biological agents and toxic chemicals. Reference laboratories are responsible for investigation and/or referral of specimens. They are made up of more than 100 state and local public health, military, international, veterinary, agriculture, and food- and water-testing laboratories. In addition to laboratories located in the United States, facilities located in Australia and Canada serve as reference laboratories. Sentinel laboratories are hospital-based, clinical institutions, and commercial diagnostic laboratories. These sentinel laboratories now play a key role in the early detection of biological agents. Sentinel laboratories provide routine diagnostic services, rule-out, and referral steps in the identification process.¹⁵

Integration of Civilian and Military Medical Intelligence

In order to investigate unusual epidemics, we require information about the ecological and biologic characteristics of the pathogen, the natural routes of infection, the pathogenesis, the clinical picture and immunology of certain diseases, the epidemic foci, and the special characteristics of an artificial dissemination of this pathogen. It is also essential that there is an adequate and efficient field analysis of the epidemic, an examination of the clinical picture and the epidemiologic situation, and a collection of representative samples and data for statistically sound epidemiologic, epizootiologic, medical, and laboratory analysis. This necessitates properly trained mobile investigation teams with appropriate technical equipment. In order to be the most effective, these teams must include both civilian and military forces.¹⁰

There is now a growing integration of civilian and military medical intelligence systems. One example is the DoD laboratory-based global influenza surveillance system. Military global influenza surveillance began in 1976 as an Air Force program.²⁴ In 1996, President Clinton issued Presidential Decision Directive NSTC-7, which formally expanded the mission of the DoD to support global surveillance, training, research, and response to emerging infectious disease threats.²⁵ As a result, the efforts of national surveillance programs, overseen by the World Health Organization (WHO) and administered by institutions such as the CDC, the U.S. armed forces and 60 to 70 collaborating laboratories annually culminate in the development of effective influenza vaccines.²⁶

Another indication of further integration of U.S. civilian and military medical intelligence systems is that of the U.S. military officer participation in the CDC Epidemic Intelligence Service (EIS). Although the EIS was born in 1951 (in part because of a perceived biological warfare threat), the U.S. military did not participate actively in EIS

until 1994. Since then, military officers have had a growing presence in EIS and the DoD has a permanent liaison stationed at CDC. From a national perspective, this collective benefit in epidemiological judgment and networking will specifically contribute to the execution of various national plans to defend against biological attacks.²⁷

Medical Intelligence and Risk Management

Risk assessment is a systematic process for quantifying the likelihood of adverse health effects in a population following exposure to a specified hazard. A risk assessment is a decision-making support tool used to establish requirements and prioritize program investments. Analytical risk management is the process of selecting and implementing prevention and control measures in order to achieve an acceptable level of that risk at an acceptable cost (Table 55-3).

It is impossible to avoid all possible risk of terrorism. Compared with risk avoidance, which seeks to counter all possible vulnerabilities, risk management instead weighs the risk of loss against the cost of control measures. Risk management is composed of three main elements: risk assessment, cost-benefit analysis, and risk communication. The components of analytical risk assessment with regards to terrorism include asset and loss impact assessment, threat assessment, and vulnerability analysis.²⁸

Accurate threat assessment can only come from the military and intelligence community. Thus, well-integrated medical intelligence provides the preexisting public health and intelligence systems with the ability to recognize and characterize a population's risk for terrorism in advance of any subsequent countermeasures in the form of prevention and control. Soundly performed risk assessments help ensure that specific programs and

Intelligence and law enforcement threat information is a key input into a risk assessment process. Risk assessments are widely recognized as valid decision-support tools to establish and prioritize program investments and are grounded in risk management

Medical intelligence may be applied within the process of analytical risk management in an effort to better protect and defend both civilian and military populations against terrorism. The intelligence community has produced National Intelligence Estimates (NIE) and other high-level analyses of the foreign origin terrorist threat that include judgments about the more likely chemical and biological agents that would be used. An NIE is intended to help decision-makers think through critical issues by presenting the relevant key facts, judgments about the likely course of events in foreign countries, and implications for the United States.

A threat analysis—the first step in determining risk—identifies and evaluates each threat on the basis of various factors such as its capability and intent to attack an asset and the likelihood and the severity of the consequences of a successful attack. Valid, current, and documented threat information, including NIEs, in a risk-assessment process is crucial to ensuring that countermeasures or programs are not based solely on worst-case scenarios and therefore out of balance with the threat. Risk-management principles acknowledge that (1) although risk generally cannot be eliminated, it can be reduced by enhancing protection from validated and credible threats, and (2) although many threats are possible, some are more likely to be carried out than others. Risk assessments form a deliberate, analytical approach that results in a prioritized list of risks (i.e., threat-asset-vulnerability combinations) that can be used to select countermeasures to create a certain level of protection or preparedness. Because threats are dynamic and countermeasures may become outdated, it is generally sound practice to periodically reassess threat and risk. To perform a realistic risk assessment of terrorist threats, a multidisciplinary team of experts would require several inputs, including written foreign and domestic threat analyses from the intelligence community and law enforcement as well as civilian public health and medical intelligence.

PITFALLS

Less-than-Complete Integration of Veterinary Medicine into Medical Intelligence Systems

Although recent reports have emphasized the need for improving the ability to detect a biological terrorist attack on human populations, the use of veterinary services in this effort and the potential for the targeting of livestock (e.g., horses, cattle, sheep, goats, swine, and poultry) have been addressed only briefly. Improving

surveillance for biological terrorist attacks (that target livestock) and improving detection and reporting of livestock, pet, and wild animal morbidity and mortality are important components of preparedness for a covert biological terrorist attack. Although veterinarians have been mentioned as an integral part of biological terrorism preparedness planning, the importance of improving surveillance among livestock, pet, and wild animal populations has not been emphasized. Any improvement in detection of a covert biological terrorist attack should be a goal of human and veterinary health programs. Although a system for detecting and reporting nonendemic or foreign animal diseases exists in the United States, the system needs strengthening to increase the likelihood of detecting a covert biological terrorist attack on humans or other mammals. Following a covert bioterrorist attack with an agent targeting livestock or human populations, the front line of practicing human and veterinary healthcare providers will be essential for detection, reporting, and response.³⁰

Inherent Difficulties in the Natural Course of Bioterrorism-Related Illness

Inherent difficulties in the natural course of bioterrorism-related illness may limit the use of medical intelligence to rapidly recognize the clues of a bioterror attack. In one example, the steep epidemic curve expected in a bioterrorism attack is similar to that expected with other point source exposures, such as foodborne outbreaks.⁸

Even in the presence of known indicators of bioterror attack, it may not be easy to determine that an attack occurred through nefarious means. For example, in spite of a CDC-led investigation, it took months to determine that an outbreak of salmonellosis in Oregon was caused by intentional contamination of salad bars.³¹ Other naturally occurring outbreaks such as the hantavirus outbreak in the Four Corners area of the United States³² and the tularemia outbreak in Kosovo, have been mistakenly thought of as possible results of intentional contamination.¹⁰

Lack of Clinical Training Among Medical Personnel

Lack of clinical training among medical personnel with respect to illness related to chemical and biological terrorism may limit the timeliness of medical intelligence. Even emergency medicine residency training programs have exhibited a less-than-optimum capability for training physicians to diagnose and treat these rarely seen maladies.³³

Challenges Involving Integration of Civilian and Military Medical Intelligence

There may also be challenges involving the integration of civilian and military medical intelligence. This first became obvious with respect to national terrorism response during the 1996 Centennial Olympic Games in

Atlanta, Georgia, when unprecedented preparations were undertaken to cope with the health consequences of a terrorist incident involving chemical or biological agents.^{34,35} Local, state, federal, and military resources joined to establish a specialized incident assessment team and Science and Technology Center.³⁵ Before the Atlanta Olympic Games, however, only certain specialized units within the military and the law enforcement communities were prepared to cope with chemical or biological agents. The literature that dealt with protecting the public health at large events did not address terrorism or these agents in any detail. There was no single plan or organization to guide response preparations. The city of Atlanta had little indigenous capability to recognize or deal with terrorism involving chemical or biological agents. Efforts undertaken to cope with chemical or biological terrorism for the Olympic Games were therefore the result of the federal plan plus the diverse initiatives of many organizations and agencies from both within and outside of the city.

A Science and Technology Center was created at the CDC, which was conveniently located in Atlanta, to provide emergency public health, medical, toxicologic, forensic, and scientific consultation after a suspected terrorist event involving chemical or biological agents. The Science and Technology Center was closely linked with the FBI assessment team and included representatives from a number of the environmental and infectious disease laboratories at CDC, the Agency for Toxic Substances and Disease Registry, and the military.³⁵

The Center also had representatives from the local public health and emergency medicine community. Almost all of the major federal and military organizations in the United States that would have had a role in responding to a chemical or biological terrorist incident were deployed to Atlanta during the Olympic Games. Before this time, few of these organizations had ever collaborated to respond to a terrorist action, nor had many worked with local emergency response personnel. The Games served as an unprecedented opportunity to develop and realign integrated response plans through daily interactions, formal planning sessions, tabletop exercises, conferences, and field exercises. The event also served as a precedent for the integration of civilian and military assets within the context of Presidential Directive 39³⁶ into a configuration that would later evolve into the current National Response Plan.³⁷ Subsequent reviews of this historic benchmark event have described challenges involving the integration of civilian and military medical intelligence.^{34,35} The issue of coordination was again encountered during the anthrax mail attacks of 2001.

Inherent Difficulties of Syndromic Surveillance

Inherent difficulties of syndromic surveillance may limit usefulness of early warning of outbreaks related to a bioterror attack. Passive disease-reporting systems not directly linked to the laboratory could result in delays in the recognition of disease outbreaks. Other difficulties with current surveillance systems include: incomplete

data capture; inaccurate data; gaps in provider appreciation for the importance and usefulness of surveillance activities, data, and information; difficulty in geographic localization of an outbreak and tracking geographic locations of patients; inadequate indicators to serve as triggers for a response; limited surveillance of response personnel; limited feedback to reporting installations; and suboptimal laboratory integration.⁶

The signs of terrorist attack may also appear insidiously, with primary-care providers witnessing the first cases. However, it may not even be emergency room personnel who first detect a problem. The first to notice could be a hospital laboratory seeing unusual strains of organisms, a county epidemiologist keeping track of hospital admissions, a pharmacist distributing more antibiotics than usual, a 911 operator noticing an increase in respiratory distress calls, or a funeral director with increased business.⁸

Despite the small number of patients, the published descriptions of 11 persons with inhalational anthrax in the United States may offer four lessons for detecting a bioterror epidemic.¹² First, a key objective of syndromic surveillance is to detect early-stage disease, but fewer than half of these patients sought care in the early stage of illness before hospitalization was necessary. Second, emergency room data are a common source for syndromic surveillance, but detecting an increase in visits coincident with hospital admission may not provide an early warning because the time needed to process surveillance data and investigate suspected cases would be at least as long as the time for admission blood cultures to be positive for *Bacillus anthracis*. Third, the four patients who received early care and were discharged to home were assigned three different diagnoses, which suggests that syndromic surveillance systems must address the potential variability in how patients with the same infection may be diagnosed during the prodrome. Finally, rapid diagnosis after hospitalization was possible only in those patients who had not received antibiotics before cultures were taken.

Thinking Outside the Box: Health Service Support Considerations in the Era of Asymmetrical Threats

Pietro D. Marghella and Duane C. Caneva

When the Cold War effectively ended in the early 1990s, it marked the passing of an era in warfare. For generations, we had become used to viewing the spectrum of warfare from a traditional and symmetrical linear perspective. As events progressed in intensity, so did the population-at-risk (i.e., those involved with the prosecution of a battle) and the level of expected casualty production. In the linear threat environment (which traditionally constitutes force-on-force engagements), where casualty models based on reliable sources and a similar historic event could be used to determine scope, scale, and timing of expected casualties, medical planning simply involved constructing an adequate health service support architecture to support the population-at-risk based on the level of intensity they expected to incur in the operational environment.

The last quarter of the twentieth century bears witness to a shift in the prosecution of warfare away from those traditional linear events to one dominated by the threat of asymmetrical attacks. As the balance of power shifted to a sole-surviving global hegemon (the United States), rogue nations and nonstate actors wishing to influence world affairs or advance their political or religious goals realized that the only way to strike at their enemies was through the use of terrorism, which by definition is non-linear or asymmetrical in its approach. A further evolution of this strategy, termed *fourth generation warfare*, postulates that the driving factors of this global transition are more than the progression from the industrial age to the information age, but include political, social, and economic factors. The threat consists of an enemy made up of loosely associated groups or franchises of cells that are bound by common goals, if not ideology. They leverage various networks available in the information age to attack our new center of gravity—political will. They are skilled in using to their advantage the endless news cycles, legitimate-appearing organizations, lobbying efforts, support and encouragement from useful idiots, and even political donations or lobbying to peddle influence, sway public opinion, and effect outcomes favorable to their cause. The tactics result in an increased risk of

asymmetrical attack in the face of partisan discord in the political arena and divided public opinion.¹

To complicate matters even further, chemical, biologic, radiologic, nuclear, and high-yield explosive (CBRNE) weapons of mass destruction (WMD) have entered the scene as the potential “weapon of choice” for terrorist organizations, which seek to inflict the greatest possible damage on their targets in hopes of creating large-scale conflagrations that cause second-, third-, fourth-order, or even higher, cascading effects (e.g., medical, political, economic, international events) and unintended consequences. It appears that the most fervent hope of terrorist organizations is to create so significant a set of ripples as to upset the very order and stability of our society, to the point of bringing us to the very precipice of collapse.

In the new generation of warfare, our planning for emergency management will prove challenging for several reasons:

1. CBRNE agents can cause incidents that cross the linear spectrum of casualty production relative to agent used. Terrorist organizations and rogue nonstate actors now have access to improved weapons technology and weapons with the potential for far greater impact that have been developed outside the control of state-sponsored programs through the targeting of increased population densities and by our own increased reliance on critical infrastructures in our society. Further, some terrorist groups no longer seek to cause terror as the sole end, but seek to kill as many people in their target population as possible.
2. There are no useful casualty rates to extract from CBRNE environments, hence no empirical data to determine what the event will look like relative to casualty production.
3. CBRNE mass casualty incident requirements (e.g., “detect to determine work environment”) differ from military nuclear, biologic, and chemical defense conducted on the battlefield (“detect to avoid”) and from hazardous materials response (“detect to contain”).

4. The very nature of terrorism will mandate that emergency response measures will always be conducted in “crisis mode.” Concepts like “graceful” or “managed” degradation of the standards of care that should be addressed in preincident planning will most certainly have to be considered under the constraints of the crisis, when there is little room for thoughtful consideration. Self-organization of response components will need to occur in response to chaotic conditions set by the incident.
5. The potential for catastrophic casualty events will be high, especially if nuclear or biologic agents are employed. As terrorists become emboldened—or desperate—the very fact that the majority of their potential targets live in free and open societies only enhances the opportunity to create such nightmarish scenarios, especially as access to increased weapon technology progresses and our population densities remain static in high-threat locations. Given these assumptions, emergency planning should assume that response and support infrastructure would be significantly stressed from the onset of an attack.

From here on in, we enter into a new set of assumptions about the world we live in and how we intend to prevent, prepare for, and mitigate the threats we now face. First, it is important for us to accept what we would have previously considered absurd in terms of threats is now entirely possible. In the post-9/11 era, we face scenarios that could make the events of *that* fateful day pale in comparison. Second, we have to recognize that another attack (or attacks) could occur at any time, anywhere around the world. Indeed, intelligence services tell us (in open-source literature) that one of the preferred methods of inciting terror and mass panic is multinodal, simultaneous targeting against multiple sectors of critical infrastructure to enhance the systemic impact of the event and maximize the stress on our collective response network. And third, we have to recognize that we are just not collectively prepared to deal with a high-end attack. Disaster management for high operational to strategic level events is simply too immature to assume that we would capably and adequately handle an event that has few, recent U.S. historical precedents.⁸ Hence, there is a pressing mandate for us to consider alternative strategies for complex emergency and disaster management, strategies that move away from the traditional, linear, and symmetrical approaches we have historically employed in the emergency response arena. It’s time to enter the environment “outside the box.”

WHAT’S OUTSIDE THE BOX?

The phrase “thinking outside the box” has long been a mantra of the business community to discourage managers and executives from becoming too lock-step (or

Catastrophic Casualty Events (CCE) are stratified at three levels: Level I, up to 1000 casualties; Level II, up to 10,000 casualties; and Level III, above 10,000 casualties. For the purpose of this discussion, the authors argue that any attack at Level II or above will tax our emergency response systems to the point of corruption.

linear) in their approach to standards of acceptable business practices. Above all, thinking outside the box promotes the notion of the paradigm shift, which seeks to break away from a standards-based approach in which rigorous statutes are followed without deviation. Performing qualitative and quantitative risk assessments, leveraging the collective experience and expertise of the emergency management community, and demonstrating a willingness to take greater risk for potentially much greater benefit, indeed, operating on the edge of chaos,² is clearly the order of the day in the new threat environment in which we now find ourselves. It also represents an opportune time to identify—indeed create, if necessary—the unrecognized dimensions and disciplines (the “unknown unknowns”) that may prove to provide the solution sets we need to assuage these threats. To this end, the following out-of-the-box strategies are offered for consideration.

Be Practical

Our approach to complex disaster and emergency management has to be pragmatic. As a human species, we have a nearly reflexive way of ignoring the potential for staggering calamity. Maintaining a mental attitude of “If I don’t think about it, perhaps it will go away!” is indeed a dangerous perspective to keep when there is more than sufficient evidence that our enemies wish to do us great harm. A common progressive rationalization process is thinking that “It won’t happen; or, it won’t happen to me; or, it will happen to me but won’t be severe; or, it will happen to me and be severe, but somebody else will rescue me.” It is equally dangerous to engage in a pessimistic approach when planning for catastrophic attacks that produce strategic-level casualty streams. If we simply assume that our collective response resources are going to implode under the weight of an event, we ignore the opportunity to take qualitative measures to improve our level of preparedness through pre-event (deliberate) planning and resource building—the greater the effort made in developing response capabilities, the higher the threshold at which the system fails.

The public health, medical, and emergency response communities that will bear the most weight of the emergency management mission must ignore the tendency to view the world through rose-colored glasses. Certain scenarios that are deemed plausible *are* indeed chilling to think about. An improvised nuclear weapon detonation in a major metropolitan area, or the dissemination of a biologic agent that causes a widespread outbreak of a highly lethal disease, are incredibly frightening to consider, but consider them we must because these scenarios are entirely plausible in today’s threat environment. Plausibility—no matter how extreme—must drive what we prepare for, and facing the threats head on will be the only way we are able to increase our level of preparedness.

Be Proactive

Homeland Security Presidential Directive 5 mandated that the U.S. Department of Homeland Security (DHS) develop the National Incident Management System

(NIMS) and designated the DHS as the primary agency for homeland security issues. The NIMS has established pillars of emergency management and disaster preparedness as preparedness, prevention, mitigation, response, and recovery, and mandates that the DHS develop an NIMS Integration Office to coordinate and integrate across these pillars nationally. It follows, then, that our planning be proactive versus reactive, with much to do preincident. Proactivity in the complex emergency and disaster management arena equates to considering the notion of deliberate planning as a very important tool in the planner's kitbag. Deliberate planning before an event allows us the time to expend intellectual capital on the various scenarios of concern on the CBRNE WMD threat environment. It provides us with an opportunity to consider how the complex mix of response assets and protocols, equipment, and logistical resources can all be coordinated to be in the right place at the right time to help facilitate response. Done right, deliberate planning flows directly into crisis action planning as soon as either an event trigger is noticed or an actual event occurs. Skilled emergency planners and managers recognize that once an actual situation develops, planning becomes fluid, and in some cases, many of the response accommodations made in the deliberate phase may no longer be applicable. As is often stated, it is not so much the plan that is important but the planning process; however, it is far easier to flex an existent plan to an unfolding event than it is to develop a plan from scratch the moment an attack or complex emergency occurs. Simply being reactive to an emergent event is a recipe for disaster, since disasters are multidimensional and create far too much "fog" to ever sort out in a sufficient period to effectively mitigate the impact.

Avoid Duplicating Efforts

The previous point leads to the issue of economy of effort. Justifying the resources required to prepare against terrorist attacks can be a challenge in appropriating the capital, time, and other scarce resources. However, numerous arguments and examples exist that support such efforts being a routine part of strategic planning for any business, sector, enterprise, or agency as well as identifying funding sources for capabilities.^{3,4}

Such topics as continuity of operations, critical infrastructure protection, or protection of mission-critical resources are just as important in government, military, or business sectors, although the economic benefit derived by these practices may not be initially obvious. Identifying these benefits and recognizing the randomness of complex emergencies and the unintended consequences that can snowball or cascade into second-, third-, or higher-order effects of catastrophic event requires significant insight, experience, and expertise but represent good and necessary business practices. Developing and maintaining a robust medical system able to sustain an adequate response capability represents a benefit to society at large, and funding and support sources should reflect this.

Disperse Resources

From a logistical perspective, it further follows that we consider moving away from centralized resource management to dispersed resource management relative to catastrophic emergency response. Former Commander of the United States Pacific Command Admiral Joseph Prueher wrestled with the challenges of having the largest geographic combatant command area of responsibility of all of the U.S. Combatant Commanders. To describe the challenges he faced in theoretical terms, he coined the notion of the "tyranny of distance" relative to the rapidity of response. Simply put, the farther your response resources are from the event, the longer it will take to get those resources to an affected population; hence, your ability to adequately respond will be proportionately diminished.

The dispersed prepositioning of the Strategic National Stockpile (SNS) is an excellent demonstration of how to overcome the challenges to rapid response. The DHS and the Department of Health and Human Services recognized that a centralized location of the stockpile could be detrimental to rapid response distribution to an affected locale. To better facilitate distribution, the stockpile was broken down into 12 geographically disparate locations around the United States, with organic movement resources to facilitate distribution in the wake of an event. Following suit by prepositioning other response assets (including stockpiles of minimal care beds and healthcare staff to support large populations affected by an attack or disaster) would help in minimizing the impact of the tyranny of distance and would improve overall response capabilities. The SNS "ChemPack" program illustrates this principle even further for the example of a chemical attack, placing time-critical supplies closer to where they might be needed.

Expand the Medical Infrastructure

In formulating plans for managing catastrophic casualty events, it will be necessary to break the medical paradigm that relies on hospitals for the management of casualties and constitutes a rigid standard of care. With the advent of managed care in the last quarter of the twentieth century as a nearly universal approach to the provision of hospital-based medicine in the United States,⁵ the notion of "available beds" for disaster and emergency situations has dissolved. It should now be considered a false expectation that hospitals (as finite physical structures) will be capable of taking on casualties from an event that could produce sudden spikes of thousands, if not tens of thousands or more, victims. In all likelihood, these resources would collapse under the weight of even a moderate event, essentially eliminating the most important resource of an affected area's medical infrastructure—its cadre of trained professional healthcare providers. Efforts made using a multidisciplinary approach have afforded excellent guiding and design principles for hospital-based mass casualty care in response to CBRNE incidents, including issues of surge capability, optimizing productivity, leveraging on technology, and managing a degradation of capability.⁴

The solution for catastrophic-scale incidents again lies in the deliberate planning before an event occurs, when regional planners can identify “locations of opportunity” that can be used as alternate care facilities. Any physical structure that offers large open space where casualties can be directed to obtain support is a candidate for this designation; gyms, schools, shopping malls, and sports arenas all represent excellent locations for use under emergency conditions. Similarly, if basic utilities remain intact, hospitals could be established in select neighborhoods where a house serves as a ward and a block or street serves as the “hospital.” The trained professional staffs of regional medical facilities can then be used to triage patients to these sites and oversee the provision of minimal care support through the use of community-based care by family and noninjured survivors. Limited staff capabilities would be addressed through various mechanisms, such as national credentialing or emergency credentialing procedures allowing for rapid credentialing of professionals provided from outside the affected region, temporary extension of current privileges under innovative supervision, longer hours, and cancellation or postponement of routine medical care. Use of paramedical or lay personnel with on-the-job training, and again, innovative supervision, could also provide additional caretakers. Coupled with the repositioning of minimal care beds as mentioned above, this strategy could be useful in preserving the community’s medical infrastructure while still offering a viable way of handling potentially catastrophic casualty streams. Such “off-site” care facilities would require additional, complex coordination with the regional health-care community through critical functions including information and communications, transportation, logis-

tics and supply, government services, mortuary affairs, and a host of public health services making for an extremely challenging situation. Although degradation in the standard of care would be anticipated and difficult to determine ahead of time, this issue, as well as credentialing and privileging issues, should be addressed as part of a national strategy.

Network Multidisciplinary Resources

Identifying not only the multiple disciplines necessary in developing response capability, but also the multiple dimensions and layers of planning required across preparedness, prevention, mitigation, response, and recovery phases of emergency management must be explored. Response occurs not only within the wire diagram framework of the Incident Command System, but, depending on size and scope, occurs functionally across sectors, critical infrastructures, industries, and complexes in conjunction with government agencies, non-governmental organizations, and the citizenry. Perhaps the greatest asset in industrialized nations is industry itself, with its innovators and entrepreneurs. Table 56-1 compares various emergency management functions, emergency support functions, and critical infrastructures likely to form the complexes with a role in emergency management. Such complexes overlap and must be networked.

Within the medical complex are different dimensions such as emergency medical services; the medical treatment infrastructure; public health departments; the pharmaceutical industry; the diagnostic equipment industry; the laboratory, medical logistical, and supply industry; and care providers and technicians. In its entirety, the med-

TABLE 56-1 COMPARISON OF EMERGENCY MANAGEMENT FUNCTIONAL AREAS, EMERGENCY SUPPORT FUNCTIONS, AND CRITICAL INFRASTRUCTURE SECTORS

EMERGENCY MANAGEMENT FUNCTIONAL AREAS*	NRP EMERGENCY SUPPORT FUNCTIONS†	CRITICAL INFRASTRUCTURE SECTORS (PDD-63)‡
Command staff	Transportation	Information and communications
Fire and emergency services	Information technology and communications	Banking and finance
Emergency medical services	Infrastructure	Water supply
Security/law enforcement	Firefighting	Transportation (aviation, highways, mass transit, rail, waterborne, pipelines)
Explosives ordnance disposal	Information and planning	Emergency law enforcement services
Public works	Mass care, housing, human services	Continuity of government services
Public affairs	Resource support and logistics management	Emergency fire services
Mass care	Public health and medical services	Public health
Health service support	Urban search and rescue	Energy (electric power, oil, and gas production and storage)
Occupational safety and health	Hazardous materials response	Special functions
Industrial hygiene	Food and agriculture	Law enforcement and internal security
Meteorology and oceanography	Energy	National defense
Supply and logistics	Law enforcement	Foreign affairs
Mortuary affairs	Economic stabilization, community recovery, and mitigation	Foreign intelligence
Emergency response teams	Emergency public information and external communications

‡PDD-63, Presidential Decision Directive-63, May 22, 1998.

ical complex represents a powerful capability if it is coordinated across public, private, and government assets at local, regional, state, and federal levels; however, it must also network with other complexes including security/law enforcement, emergency and fire services, government, supply and logistics, the general public, media, and transportation, and it must do so with the right processes, disciplines, and specialists in all five phases of emergency management. As an example, medical syndromic surveillance must be integrated with surveillance in other areas such as law enforcement, intelligence, food, water, transportation, education, and the public and private sectors, and how these sectors interrelate needs to be explored.

Explore Capabilities to Handle Mass Casualty

One area of discipline that needs further development is the study of mass casualty care. Development, evaluation, and validation of tactics, techniques, and procedures used for the triage and treatment of mass casualty victims in chaotic, perhaps even contaminated environments needs to be done using the scientific method, and progression from consensus-based guidelines to evidence-based practices must be made a priority. Such issues as triage, mass casualty airway management, or mass casualty decontamination techniques, and the ability to correlate response requirements with resources and capabilities in real time, represent some of the areas in need of further study.

Provide Emergency Management Training

We need to identify standard training requirements and positional competencies for key roles in our emergency management programs. This would include training for emergency response personnel tailored to their specific needs but standardized for that sector or industry, and this must be affordable and available locally. Required sustainment training should include practical application of skills in evaluated exercises and not just training on individual response equipment. Advanced training should be developed for a portion of those (perhaps 20%), advancing their skills and enabling them to act as “force multipliers” or “self-organizers” during practical application exercises and enabling them to lead squad-level teams in the Incident Command System in the response phase. Expert-level “train the trainer” training for a select number should include advanced “live fire”-type training and enable these responders to lead at the group, departmental, or division level in the Incident Command System during the response phase. Finally, and most importantly, this training should be institutionalized and incorporated into academic curricula using national standards.

Educate the Populace

Taken one step further relative to training, there is a need to train or, at least, sensitize the population on how complex emergencies and disasters will be managed, including

where to access medical care after an event has occurred. It will require a significant, national-level effort to set an initiative of this level in motion. At the height of the Cold War, our national civil defense program was the mechanism by which we educated, trained, and sensitized our nation to the omnipresent threat of nuclear attack. Many of us who came of age in this era can well remember the authoritative voice over the radio announcing “THIS IS A TEST OF THE EMERGENCY BROADCAST SYSTEM”; the sound of the weekly civil defense siren; and the ubiquitous duck-and-cover drills requiring us to dive under our school desks at a moment’s notice. Although to some a wistful memory of their youth and a bygone era, these now represent a “back-to-the-future” concept of emergency preparedness we must embrace if we are to prepare our citizenry for the inevitability of a calamitous event, whether it is natural or manmade. Our national leadership has to lean forward to reinvigorate a civil defense program that provides education, training, and substantive direction on how to enhance our individual survivability. They should leverage the proliferation of media platforms that can carry the preparedness message, including television, radio, and the World Wide Web. Civil defense preparedness has to be reinducted into our population, lest we again be caught off guard the next time an attack or disastrous event occurs.

Develop the Preparedness Architecture

Finally, we need to take the steps necessary to complete the national response and preparedness architecture. When DHS Secretary Tom Ridge announced the increase in the national threat level on December 21, 2003, it set into motion a unique and historically unprecedented planning evolution that culminated in the fielding of the Catastrophic Incident Response Annex Supplement (CIRAS) of the National Response Plan (NRP). This plan now describes how the collective federal partner agencies will respond to assist state and local authorities with the management of a catastrophic casualty event. Although significant as a first-order effort to put our collective arms around newly emerging threats, there are still overall gaps in our planning architecture due to the fact that the state and local strata of response have not yet developed supported and/or supporting plans to the national-level initiatives of the CIRAS/NRP. To help enhance the effectiveness of our response and preparedness efforts, there needs to be as seamless an architecture as possible between those three levels of response. Failing to coordinate our consequence management strategy is a recipe for chaos and failure at the moment of execution, and it should at all costs be avoided.

CONCLUSION

Prior to September 11, 2001, using phrases like “thinking outside the box” would have been considered trite by any standard and would likely have relegated the writer to the ranks of the new-idea and catch-phrase challenged. Since that time, America’s perception of the

world has changed in a way so dramatic that even the most prescient prognosticators of global events could not have possibly predicted. Given that fact, any decision on how to approach these dramatic shifts that doesn't rely on thinking outside of the box dooms us to failure from the start for one glaringly simple reason: all of the strategies developed for complex emergency and disaster management in the pre-9/11 era would never have offered useful solution sets for the scope and scale of events that we believe will now have reasonable expectation to occur. The challenge is to develop adequate policy, doctrine, and strategy for the conduct of our crisis response and consequence management efforts in the face of the present threats. Emergency preparedness professionals must consider adopting new approaches to the management of these events if we are ever to achieve success in the new threat environment.

Accidental Versus Intentional Event

Joanne Cono

Not all disasters are easily recognized in their early stages. Although disasters caused by weather events (e.g., tornadoes, hurricanes, lightning), geologic events (e.g., earthquakes, volcanic eruptions), and some technologic events (e.g., bomb explosions, nuclear reactor accidents, structural failures) are quickly attributable to a physical source, other disasters such as acts of biologic, chemical, or radiologic terrorism may not be readily recognized or characterized.¹ Recognizing and responding to these types of disasters requires patience, a high index of suspicion, clinical astuteness, and rapid epidemiologic assessment and response. Disasters that manifest with physical illness in a population may go unrecognized over a period of time and not become apparent until many persons become ill or die, or the contaminating or infectious agent is identified as one that does not commonly occur or does not appear to be a plausible natural finding.

When an illness is attributed to an unexpected biologic, chemical, or radiologic agent, information from a detailed patient clinical and epidemiologic history is the most effective tool to distinguish “accidental” or “natural” outbreaks from “intentional” or “terrorism-related” outbreaks. Local and state public health authorities should be notified when a patient is diagnosed with an unusual illness or syndrome. Public health authorities will begin the larger-scale epidemiologic investigation and the public health response necessary to control disasters caused by biologic, chemical, and radiologic terrorism. When an intentional terrorist event is suspected, public health authorities also will engage law enforcement agencies to begin concurrent criminal investigations.

HISTORICAL PERSPECTIVE

Biologic, chemical, or radiologic terrorism is the deliberate use of any of these agents against people, animals, or agriculture to cause disease, death, destruction, or panic for political or social gains. The only factor differentiating an accidental event from a terrorist event may be the malicious intent.² Historically, there have been serious outbreaks that have been mistaken for intentional terrorist attacks and serious outbreaks for which terrorism was quickly ruled out.

Two naturally occurring infectious disease outbreaks in the United States were initially feared to be the result of terrorist attacks: the hantavirus pulmonary syndrome outbreak of 1994³ and the West Nile fever outbreak of 1999.⁴ Both were caused by newly emergent infectious diseases and required careful evaluation of clinical and epidemiologic data to assign causality. In each case, a new viral pathogen was identified that was not endemic to the United States. Both outbreak investigations yielded reasonable alternative explanations that refuted the terrorism hypothesis.

The smallpox outbreak of 1978 in Birmingham, England, is an example of an accidental outbreak that today might raise suspicions of a terrorist attack. The last case of naturally occurring smallpox anywhere in the world was diagnosed in Somalia in 1977, and endemic smallpox had not been seen in England since 1975. Ten months after the world’s last case, a 40-year-old woman in Birmingham, England, was found to have smallpox.⁵ She died 3 weeks later, but not before infecting her mother (who recovered) and perhaps her father (who, though febrile, died of myocardial infarction within the incubation period of disease). Prompt vaccination of contacts and isolation of febrile contacts quickly extinguished the outbreak. Public health investigators concluded that source of the outbreak was most likely the smallpox laboratory at University of Birmingham. The index case patient was a medical photographer who worked in an office immediately above the laboratory. Matching strains of smallpox confirmed the source, although the route of virus transmission is less certain. This was the last outbreak of smallpox in the world. In 1980, the World Health Assembly declared smallpox to be eradicated from the planet. Any smallpox outbreaks that occur posteradication most likely will be first investigated as a terrorist event.

During the anthrax attacks of 2001, the first case of anthrax was initially suspected to be a naturally occurring case.^{6,8} The index patient, a resident of Florida, traveled through rural North Carolina 3 days prior to becoming ill with inhalational anthrax, an uncommon diagnosis even in animal handlers, and an even more unusual diagnosis in an office worker. Since anthrax spores are regularly found in soil and cases can occur among persons who are exposed to animal products that have been contaminated

by soil, this particular case was investigated for sources of animal exposure. None was found. When further epidemiologic investigation revealed anthrax spores in the patient's workplace and a coworker became ill with inhalational anthrax, terrorism was recognized. In this attack, 21 persons were infected via the postal system. This case study illustrates the importance of considering terrorism when investigating outbreaks that occur in unusual geographic locations (e.g., anthrax in urban/suburban Florida), among unusual populations (e.g., office workers with no animal contact), and in clusters (e.g., more than one person in the same office).

CURRENT PRACTICE

Disease outbreaks have occurred and been investigated for many years. However, recent events such as the 2001 anthrax attacks and the 1994 and 1995 sarin gas attacks make it necessary to consider terrorism when evaluating outbreaks of infectious and noninfectious disease. A terrorist agent may be a very common organism, such as influenza or *Salmonella*, or may be a more exotic organism such as Ebola virus or variola virus.

Unusual clusters of illness may signal terrorist events that require prompt public health and law enforcement responses. Although most clusters of disease will have a source other than a deliberate act of criminal intent, terrorism should be considered in the differential diagnosis. Each situation must be evaluated based on its specific context.

As noted above, today a single case of smallpox would be immediately investigated as a case of biologic terrorism; however, some events may be more subtle. When investigating a disease outbreak, there are a number of clues that should heighten the suspicions of the clinician and epidemiologist that a terrorist attack has occurred.⁹⁻¹⁵ Because no list of clues can be all-inclusive, all healthcare providers should be alert for the possibility that a patient's condition may not have occurred through natural means.

Although terrorist attacks could ultimately affect large numbers of people, disease in a single patient may be the first clue. Disease caused by an uncommon organism, such as smallpox, anthrax, or viral hemorrhagic fever, may signal a bioterrorism event. Suspicion may be further heightened by a less common presentation of one of these organisms. For example, whereas a small number of cases of cutaneous anthrax occur naturally each year in the United States, cases of inhalational anthrax are highly unusual. Furthermore, should a disease present in a geographic location where it is not usually seen, such as anthrax in a nonrural area or plague in the northeastern United States, further investigation for the possibility of bioterrorism is needed. Unexpected seasonal distribution of disease, such as influenza in the summer or antiquated, genetically engineered, or unusual strains of infectious agents may also be clues. Multiple unusual or unexplained diseases in the same patient may indicate that multiple organisms or substances were used in an intentional act, as could disease presenting in an atypical age-group or population, such as anthrax in children or varicella-like rashes in adults.

When a disease strikes more than one person, additional clues may arise. Large numbers of cases of unexplained disease or death may signal bioterrorism, as may an unexplained increase in the incidence of an endemic disease that previously had a stable incidence rate. If an unusual condition strikes a disparate population, such as respiratory illness in a large population, this may signal the release of a biologic agent, as would a large number of people seeking medical care at a particular time, signaling they may have been present at a common site when an agent was released. Likewise, large numbers of persons presenting with similar illnesses in noncontiguous regions may be a sign that there have been simultaneous releases of an agent. Finally, animal illness or die-off that precedes, follows, or occurs simultaneously with human illness or death may signify the release of an agent that affects both animals and humans.

When there is no other explanation for an outbreak of illness, it may be reasonable to investigate terrorism as a possible source. Common sources of exposure to an agent may include food and water that has been deliberately contaminated, respiratory illness due to proximity to a ventilation source, or the absence of illness among those in geographic proximity but not directly exposed to the contaminated food, water, or air.

Each event must be evaluated in context. Terrorism is still the least common explanation for disease, and other more common explanations should be evaluated and ruled out. Clues that may raise the suspicion that an intentional event has occurred can be broken down into some general categories: epidemiologic, unusual variations in disease outbreaks, unusual characteristics of disease, and animal signals.

Epidemiologic Clues

- A single case of an unusual disease, such as plague, smallpox, or anthrax, without an acceptable epidemiologic explanation
- Illness among persons with exposure to a common ventilation source and absence of disease among persons not exposed to that ventilation source should raise suspicions of an intentional aerosol release of an agent
- Large numbers of persons seeking care for a similar condition at the same time, which may indicate a point source
- Clusters of similar disease outbreaks in noncontiguous geographic locations, indicating multiple attacks
- Large numbers of cases of unexplained diseases or deaths

Unusual Variations in Disease Outbreaks

- Unexplained increases in an endemic illness, such as an increase in plague case in the southwest United States
- Disease occurring outside of its usual seasonal cycle, such as an influenza outbreak during the summer
- Disease occurring outside of its usual geographic distribution, such as plague or hantavirus occurring in the northeastern United States

- Disease that appears to be transmitted via common exposure to an aerosol, food, or water that may have been intentionally contaminated

Unusual Characteristics of Disease or Agents

- Isolation of a genetically engineered, antiquated, or laboratory-manufactured strain of organism
- Isolation of a weapons-grade form of an agent
- Isolation of a known organism with an unusual antibiotic-resistance pattern
- Unusual presentations of clinical disease, such as pneumonic plague (rather than bubonic plague usually caused by bites from infected fleas) or inhalational anthrax (rather than the more common cutaneous presentation)
- Common disease with a higher than expected mortality, or decreased patient response to usual treatments
- Several conditions or clinical syndromes occurring in the same patient, which may indicate genetically engineered or artificially combined agents
- Disease or syndromes occurring in unusual populations, such as outbreaks of chickenpox-like rash in adults or anthrax among office workers
- Unusual disease outbreaks that occur across a large geographic area, suggesting the aerosol release of an agent
- Similar genetic types of a pathogen identified across disparate geographic locations or at different times in the same location

Other Species Signals

- An unusual pattern of animal disease or death preceding human disease or death, or an unusual pattern of animal disease or death that follows human disease or death; both may indicate a large-scale release of an agent, with differing susceptibilities between animals and humans.
- Insect die-off or plant die-off associated with human illness may indicate an environmental chemical release in which the symptoms of human poisoning syndromes may be nonspecific.
- Physical findings in the environment such as liquid droplets or puddles, powders or dusts, vapors or clouds, or unusual odors in the vicinity of human or animal cases may indicate a release of a biologic, chemical, or radiologic agent.

Radiologic and Chemical Agents

Although these examples focus mostly on biologic terrorism, the tenets presented apply to radiologic and chemical events too. Covert radiologic events, such as intentionally hiding a cobalt or cesium source stolen from a medical facility in a public place, may expose many unsuspecting people.¹⁶ During cases of accidental exposure, involved persons again may not realize that they have been exposed, such as in the 1987 Goiania incident in Brazil, in which a canister of cesium-137 was inappropriately discarded by a cancer treatment facility. One family brought

home the sealed radioactive element and unwittingly exposed multiple family members who became ill. Neighboring families came to look at the fluorescent blue substance, some covering their skin with it. Although clinicians did not make the link to radiation exposure in this cluster of illness, the family's grandmother realized that her family became ill shortly after the radioactive canister entered their home. She surrendered the canister to health authorities, though not before an estimated 244 people in the community were exposed.¹⁷

With sufficient exposure, whether intentional or accidental, multiple persons may present with acute radiation syndrome, which during its prodromal phase is characterized by nausea, vomiting, and diarrhea that last for several days after exposure. This is followed by a latent phase, during which a patient feels well for a few weeks until obvious radiation illness begins.¹⁸ This spectrum of clinical illness can easily be confused with a self-limited gastrointestinal illness, particularly if a number of people attend the same event during which the exposure occurs and then present with gastrointestinal symptoms. A thorough epidemiologic investigation may rule out a common food source. A high index of suspicion for a radiation event should be maintained, especially when an infectious pathogen is not readily identifiable from clinical specimens. Patients with acute radiation syndrome may also experience cutaneous radiation syndrome, a dermatologic condition, consisting of erythema, pruritus, and desquamation. These cutaneous symptoms, accompanied by gastrointestinal symptoms and the absence of an infectious pathogen in a cluster of patients, may indicate a radiation exposure, whether accidental or intentional. Hidden sources of exposure usually lead to diagnostic delays. Again, prompt epidemiologic investigation of unusual cases can hasten the identification of a source, and criminal investigation is needed to determine possible intent.

Likewise, recognizing exposures to chemical agents can be challenging, even though the epidemiologic clues listed above still apply. Chemical exposures may be overt and quickly recognized, like the 1984 industrial accident in Bhopal, India,¹⁹ in which a release of methyl isocyanate killed 2500 people during the first week and an estimated 3500 more over the following 10 years. Or a chemical incident may be covert as in contamination of food, water, or consumer products.²⁰ Some exposures may cause delayed health effects, making it more difficult to identify an exposure source. Chemical exposures often cause nonspecific illnesses, or syndromes of illness that are less familiar to many clinicians. Additionally, if chemicals are mixed, classic toxicologic syndromes such as anticholinergic poisoning may not be apparent because patients may experience a broad array of symptoms rather than a single recognizable syndrome.

There are many case reports that illustrate these diagnostic and investigative challenges of chemical exposures. In the United States, in the Tylenol tampering cases of 1982²¹ and other medicine tampering cases like it,²² otherwise healthy patients who ingested cyanide-laced over-the-counter medications became seriously ill and multiple deaths occurred. In the Tylenol incident, the first two deaths were thought to be due to stroke and

myocardial infarction. But an astute clinician linked the unexplained syndromes of hypotension and acidosis in multiple family members of the first victim, and subsequent toxicologic testing revealed cyanide poisoning. This case report demonstrates the importance of considering chemical exposure when a cluster of patients presents with illness that is sudden, unexpected, and without prodrome. When clinical information does not indicate a naturally occurring disease, toxicology screening for poisoning is a reasonable next step.

Similarly, unexplained deaths or serious illness in an otherwise healthy population may indicate a chemical exposure. Over a 6-month period in 1985, 109 children were diagnosed with acute anuric renal failure at a single hospital in Haiti.²³ This condition had not been seen at the hospital in the 5 prior years. A traceback investigation revealed that these children had ingested a locally manufactured acetaminophen syrup preparation that was glycerin contaminated with diethylene glycol, the chemical used as automotive antifreeze. Ninety-nine of the children died. A criminal investigation ensued and determined that the poisoning was not intentional, but rather was caused by a departure from manufacturing quality control measures.

Pesticides are a group of toxic chemicals that are readily available to terrorists and also can accidentally contaminate the food supply, sickening large numbers of people in disparate geographic areas. In Oregon in 1985, a physician reported to the State Health Division 5 cases of organophosphate poisoning, resulting in cholinergic crisis. Epidemiologic investigation revealed that the patients had become ill after eating watermelon. Additional cases were reported in Oregon, Washington, and California.²⁴ Over 3 months, more than 700 cases were identified in 7 U.S. states, and 483 cases occurred in Canada. The outbreak was linked to aldicarb sulfoxide poisoning, a toxic metabolite of Aldicarb, the systemic pesticide that was used on the watermelons originating from California. The rapid notification of public health authorities led to timely identification of the poison, although the outbreak was protracted due to the far-reaching shipping network of the global food supply. The contamination was not found to be intentional.

In another pesticide-related case, in Michigan in 2003, 92 people became ill and 1700 lb of ground beef were recalled due to nicotine-based pesticide contamination.²⁵ However, in this case, the epidemiologic investigation identified a single supermarket source of the contaminated meat, and the concurrent criminal investigation led to the arrest of a supermarket employee who intentionally contaminated 200 lb of ground beef with Black Leaf 40 insecticide, which contains nicotine.

These pesticide contamination case studies illustrate the following: (1) clinicians should consider chemical poisoning in outbreaks of unexpected serious illnesses; (2) prompt reporting to authorities can more rapidly initiate public health response activities by linking distant outbreaks to a common source; and (3) accidental and criminal events may involve the same clinical illness but can be distinguished by epidemiologic and criminal investigations.

PITFALLS

There is no one algorithm that can determine whether a biologic, chemical, or radiologic disaster is naturally occurring, accidental, or intentional. Situations in which multiple agents have been used may be more difficult to recognize and may pose a greater diagnostic challenge, but once identified may be more easily characterized as intentional. Certain terrorist events will remain difficult to detect; however, through careful evaluation of all epidemiologic clues and a thorough outbreak investigation, it is possible to make educated decisions that will permit the public health and law enforcement emergency responses necessary to limit the damage caused by an intentional disaster.

Multimodality, Layered Attack

Nicholas Vincent Cagliuso, Sr.

It is thoroughly conceivable that the next major terrorist incident will include the tactic of coordinated simultaneous attacks in multiple geographic locations, both in the United States and abroad, and employ a combination of conventional and unconventional weaponry that may involve weapons of mass destruction (WMDs; i.e., chemical, biologic, radiologic, nuclear, or explosive [CBRNE] agents and devices) with the intent to kill large numbers of people over minutes, hours, or days. Then again, one need not wait until the *next* attack to witness a similar type of event. Rather, comparable scenarios have been effectively carried out for well over three decades, resulting in both the deaths of thousands and the long-term psychological impacts that terrorists so eagerly desire. Near-simultaneous or simultaneous attacks, as witnessed most recently in the Madrid, Spain, train bombings in March 2004 and on Sept. 11, 2001, when multiple hijacked aircraft were used as missiles in New York, Washington, DC, and Pennsylvania, have been used with great success by terrorists, particularly when conventional tactics (e.g., small arms, incendiaries, and explosives) are used. This chapter takes the notion of near-simultaneous or simultaneous attacks one step further by adding to them the coordinated application of a CBRNE agent in the minutes, hours, or days after the initial attack and applies to them the term *multimodality, layered attack*. Here, instead of the perpetrators targeting locations with a similar threat, they select several types of attack modes. The Iran-Iraq War of the 1980s provides one glaring example of these tactics that illustrates the implications to the both the prehospital and hospital communities.

Given the tactics employed during recent terrorist events and terrorists' drive to continually expose their targets' vulnerabilities, a newly focused attention and need for an intellectual and practical drive toward understanding multimodality, layered attacks more keenly is warranted and is examined here.

The Notion of Terrorism

To understand the concept of multimodality, layered terrorist attacks, a baseline established by an agreed-upon definition of terrorism itself must exist. Although there is no universally accepted definition of *terror-*

ism,^{1,2} this chapter uses the U.S. Department of State's definition found in Title 22, Chapter 38, Sec. 2656f³ of the United States Code that states, "the term 'terrorism' means premeditated, politically motivated violence perpetrated against noncombatant targets by subnational groups or clandestine agents." Attention is brought to the terms *premeditated* and *noncombatant targets*, highlighting that events of this kind are not accidental (see Chapter 57, Accidental versus Intentional Event) and are aimed at civilians and off-duty military personnel.

Modes of Attack

Given the variety of motives for and classifications of terrorism, a discussion of which is beyond the scope of this chapter but is treated in other parts of this textbook (see Chapters 55 and 56), a review of the two primary modes of terrorist tactics—conventional and unconventional—follows, with special consideration given to simultaneous deployments within each.

Conventional Tactics

Conventional or traditional attack modes include those attacks that do not involve WMD. Rather, small arms, explosives, and incendiary devices are used, and as recent terrorist events indicate, these devices have had a more significant impact than those that include WMD.⁴ As demonstrated by the August 2004 increase in the terror threat level for the financial services sectors in New York, New Jersey, and Washington, DC, intelligence continues to suggest that the use of the tried-and-true conventional weapons (e.g., truck bombs) are likely to remain a favored choice of terrorists. Examples of such incidents include the bombings at the World Trade Center in New York City in 1993 and the Alfred P. Murrah Federal Building in Oklahoma City in 1995, which collectively resulted in the deaths of 174 persons.

Unconventional Tactics

Unconventional or WMD attack modes involve the use of chemical, biologic, radiologic, nuclear, and high-yield explosives (CBRNE) devices.

Chemical attacks (see Section 9) have included the release of the nerve agent sarin in Matsumoto, Japan, in 1994 and again in the Tokyo subway system in 1995 by the Aum Shinri Kyo cult. Despite the cult's considerable financial wealth, the technical expertise that it could call on from its well-educated members, and the vast resources and state-of-the-art equipment at their disposal, the group could not carry out even a single truly successful chemical or biologic attack.⁵ Even the sarin attack on the Tokyo subway would be laughable if not for the tragic deaths of 12 persons and the physical and psychological harm caused to many more victims.

Biologic incidents (see Section 10) include the fall 2001 anthrax attacks in Florida, New York City, New Jersey, Washington, DC, and Connecticut where contaminated letters were processed and sent to media outlets and elected officials through the U.S. mail. Although the use of biologic weapons by terrorists has the potential to harm and kill thousands of people,⁶ the extent to which incidents involving weapons of this sort, such as the dissemination of anthrax or smallpox, will occur in the future in the United States or elsewhere is unknown. This is in part because terrorist attacks with biologic weapons have been extremely rare.⁷ However, when examining multimodality, layered attacks, one must note that the line between chemical weapons and biologic weapons is being blurred by rapid developments in biotechnology and the emergence of a new generation of toxins and bioregulators.⁸ As a result, numerous implications in the detection of and response to chemical and biologic incidents are now exacerbated by the already present challenges in dealing with these incidents. Moreover, a follow-up attack that includes, for example, the release of an agent such as smallpox could pose threats to large populations because of the potential for person-to-person transmission, enabling spread to other cities and states and exacerbating what would already be a nationwide emergency.⁹ The employment of multiple chemical and biologic agents is a very likely scenario of the future, thereby challenging the medical community to be increasingly proactive in its development of appropriate countermeasures.¹⁰

Radiologic weapons (see Section 8) or "dirty bombs" (see Chapter 177) disperse radioactive materials in a conventional device such as a bomb or other explosive container. To date, the use of nuclear and related weapons has been the sole purview of nation-states.¹¹ In 1995, alleged Islamic rebels from Chechnya were reported to have buried, but not to have detonated, a 30-lb box of cesium-137 and dynamite near the entrance of a busy Moscow park. The potential use by terrorists of nuclear, radiologic, and related weapons expands the nuclear weapons threat to new actors with links to the global complex of nuclear weapons and nuclear power facilities.¹¹

Nuclear weapons release large amounts of energy and are used for large-scale destruction. A nuclear weapon was first used in warfare on August 6, 1945, when the United States exploded a nuclear weapon over Hiroshima, Japan.¹¹ There, tens of thousands of deaths were caused by the resultant ionizing radiation. Acute radiation poisoning occurs when a patient absorbs a

large amount of radiation over a short period of time, with three specific syndromes associated with radiation absorption: cerebral syndrome, gastrointestinal syndrome, and hematopoietic syndrome.¹² Those not receiving doses high enough to cause acute illness and death are at increased rates of risk for cancer and inheritable genetic damage.¹¹

The use of any or all of these attack modes is not the only issue of concern. Rather, the tactics through which they are employed, namely their use in a coordinated matter in conjunction with or following a conventional attack, is the primary issue at hand. As such, a discussion of the use of multiple modes of attack deployed in a simultaneous or near-simultaneous fashion follows.

Categorization of Simultaneous Attacks
